The author has been engaged in an investigation having for its object to determine the nature of the active principle of jaborandi, a portion of which drug had been intrusted to him by Dr. Coutinho, for the purpose. He reports the isolation of a small quantity of alkaloidal substance, which when injected into the veins of a dog caused an abundant flow of saliva.

The leaves under examination were first allowed to macerate in 90° alcohol, which treatment was continued during two months in consequence of the author's absence from home. The alcoholic liquor, which was of a green colour, was then separated from the leaves by filtration, and submitted to distillation. The addition of water to the distilled alcohol rendered it slightly turbid, indicating the presence of a little essential oil. A certain quantity of this oil was swallowed in suspension in the diluted alcohol without having any apparent effect. The taste was pungent and persistent. The residue from the distillation, allowed to stand, deposited a relatively considerable quantity of a green substance presenting all the characters of chlorophyll. After filtering, the liquid was of a reddish brown colour, had a slight aromatic odour, and after a time deposited a brown matter, which, taken up by alcohol and precipitated by water, presented all the characters of a resin; it was slightly acrid to the taste, and did not appear to have any medicinal action. A portion of the liquid was evaporated and milk of lime added, when the reddish-brown colour was immediately changed to a fine yellow.

Desiccation having been effected at a temperature not exceeding 60° C., the residue was exhausted with a great excess of chloroform. Distillation and evaporation of this liquid yielded a yellow brown glutinous, residue presenting no trace of crystallization and showing under the glass oleaginous particles. Treated with water acidulated with sulphuric acid it partly dissolved and formed a slightly brown acid and aromatic solution, which, when treated with ammonia in excess, threw down some glutinous flocks. Shaken with ether, and the ether evaporated, it yielded a viscous aromatic substance and some crystals of sulphate of ammonia.

This substance the author found to be soluble in absolute alcohol. It was precipitated by the general reagents for alkaloids, and particularly by the double iodide of mercury and potassium in acid solution. The yellowish white precipitate resembled in its characters the best defined alkaloids. The taste of this substance was acrid; with a bitter after-taste, and a small quantity which was tasted by the author was sufficient to provoke the commencement of salivation but without sweating.

To another portion of the original liquid lime was

* Abstract of a paper in the *Répertoire de Pharmacie*, March 25, 1875.

added and it was submitted to distillation. There was an abundant evolution of ammonia, and, to judge by the characteristic odour, of methylamine or an analogous base. The distilled liquor, agitated with ether, yielded a small quantity of oleaginous and viscous substance presenting all the characters of the foregoing. When the distilled liquor no longer gave any reaction of alkaloid, the residue was evaporated and dried, then treated as before with chloroform with the same result.

After treatment with chloroform, absolute alcohol removed a small quantity of resin similar to that which was deposited spontaneously by the distilled liquor. The residue, of a fine yellow colour, yielded nothing to ether. The greater portion of it dissolved in boiling water, the insoluble portion being formed almost entirely of excess of lime. The aqueous solution deposited upon cooling a small quantity of white matter which was converted by calcination into carbonate of lime. The author was not able to determine the nature of the dissolved substances, among which there was a considerable quantity of an organic acid.

The quantity of the alkaloidal substance obtained was too small to allow of a chemical examination of it; but M. Byasson concludes from his experiments that the active principle contained in jaborandi leaves is a liquid, viscous, aromatic alkaloid, having an acrid and bitter taste, and capable, like nicotine, of being carried over in distillation by the vapour of water in the presence of ammonia. The method by which it was obtained shows that it is soluble in chloroform, ether, absolute alcohol, ammoniacal water, and dilute acids; also that it is displaced by ammonia and that ether removes it from aqueous solution.

M. Byasson proposes to call this new alkaloid "jaborandine;" but, as this name has already been appropriated to the alkaloid obtained from a species of *Piper* referred to before (see p. 781), the anticipatory suggestion of Mr. Holmes that it should be called "pilocarpine" seems to be preferable.

THE PHARMACOPŒIA DOSES.

BY J. A. COPE.

The doses given in the British Pharmacopœia are intended to represent average doses, in ordinary cases, for adults, and the maximum dose given an average full dose. It should follow that the dose of a medicine and its preparations will correspond, providing those preparations depend on that medicine alone for their activity, and contain it in an equally active condition. But it will have been observed by all who are accustomed to use the Pharmacopœia, that the doses vary considerably. Sometimes the dose of a preparation will not represent more than half the dose of the medicine it contains, and yet depends entirely upon it for its value. Thus in tincture of ergot the maximum dose is one drachm, which is equivalent to about 13½ grains of ergot, but in powder or in the liquid extract the maximum dose equals 30 grains. In another case the dose of a preparation equals twice the dose of the medicine, as in tincture of foxglove, the maximum dose is 30 minims, which represents over 3 grains of the dried leaves, but under digitalis and its infusion the maximum dose equals only 1½ grains of leaves. Under aloes and its preparations the maximum dose varies from under 3 grains to 8 grains. The dose of extract of aloes is the same as that of aloes and yet it is about twice the strength. Under tincture the maximum dose represents less than 3 grains of aloes, wine 4½ grains, decoction 8 grains of extract. The maximum dose given for tincture of belladonna is 20 minims, equivalent to less than a grain of leaf; that of the extract is 1 grain, which is considered equal to 1 drachm of tincture, or three times the strength of the dried leaf. The maximum dose for tincture of nux vomica is 20 minims, equal to about 2 grains of powdered seeds; that of the extract is 2 grains, which is equivalent to half a drachm of the seeds. The maximum dose of castor in powder is 10 grains; that of the tincture represents only 2⅔ grains. The maximum dose given for chloroform is 10 minims, but that of the spirit represents only 3 minims, the tincture 6 minims, the water 5 minims. The maximum dose of conium leaves in powder is 8 grains; that of the extract, which is about four times the strength, is 6 grains. The maximum dose given for liquor calcis is 4 ounces, equivalent to about 2 grains of hydrate of lime; that of liq. calc. sacchar. is only 60 minims or less than 1 grain of hydrate of lime. The maximum dose given for rhubarb is 20 grains; that of the extract is 15 grains, and it is three times the strength. The maximum dose for tincture of henbane is 1 drachm, equivalent to about 7 grains of dried leaves; that of the extract, which is about three times the strength, is 10 grains.

The above is sufficient to show that the doses given in the P. B. do not accurately represent the therapeutical value of a preparation as compared with the medicine it is prepared from. This appears a defect in the work, likely to cause confusion and especially to pharmaceutical students who make it their text-book.

Derby.

NOTES ON ALOES WITH SPECIAL REFERENCE TO THE ACTION OF "CHANGED ALOIN" AND THE "RESIN OF ALOES."*

BY WILLIAM CRAIG, M.D., F.R.S.E., AND LECTURER ON MATERIA MEDICA.

Aloes has been used in medicine for upwards of two thousand years. It is mentioned by Pliny, the celebrated Latin historian, who lived in the first century of our era, and by Dioscorides, a Greek physician, who probably lived about the same time, and who wrote a celebrated work on materia medica. It is used as a medicine in every country where the healing art is practised. It is thus interesting both on account of its venerable antiquity, and of the universality of its employment.

Aloes, the "*aloe*" of the Pharmacopœia, is the inspissated juice of the leaves of various species of aloe.

In studying any substance of materia medica derived from the vegetable kingdom it is well to observe a certain method:—First, to ascertain the plant which yields the drug; second, the part of the plant which yields it; third, its nature and chemical composition; fourth, its preparations and doses; and, lastly, the actions and uses of the drug: in other words, its natural history, its chemistry, its pharmacy, and its therapeutics.

I am not going minutely into all of these subjects, but I will say a few words on each.

First, the plant which yields the aloes. It is the product of several species of the genus *Aloe*, plants belonging to the *Liliaceæ* of botanists. To the same order of plants belongs the *Urginea Scilla*, the plant which furnishes the well-known medicine squill.

There are two plants often confounded with the true aloë. There is, first, the aloes of Scripture, which must

* Read at a meeting of the North British Branch of the Pharmaceutical Society of Great Britain, March 26, 1875.

not be confounded with the medicinal plant of that name. The aloes of Scripture is got from the aquilaria, a tree belonging to a different order of plants, *Aquilariaceæ*. They are trees, and are dicotyledonous plants. They were famed chiefly for their fragrance, and hence "aloes, myrrh, and cassia."

Another plant often confounded with the true aloes is the *Agave americana*, American aloe. This belongs to the *Amaryllidaceæ*, the order which contains the snowdrop and narcissus. The plants of this order differ from the *Liliaceæ* in having the flower or perianth superior to the ovary, whereas in the *Liliaceæ* it is inferior; or to speak more botanically, in *Amaryllidaceæ* the ovary is inferior, whereas in *Liliaceæ* it is superior.

The agave is a well-known green-house plant, especially the variagated variety. Its foliage has considerable resemblance to that of the true aloe, but it is essentially a different plant. The flowering stem of the agave must not be confounded with the stem of the aloe. The agave has no stem or only a very short one. It has large fleshy leaves, and though said to flower in America when about eight years old, it is much longer in flowering in this country, and hence the opinion regarding it that it only flowers once in a hundred years. When it does flower it sends its flowering stalk from the centre of the leaves. This flowering-stalk grows with great rapidity, growing sometimes thirty feet in thirty or forty days. It is said that sometimes as many as 4,000 flowers are produced on one plant. After flowering the plant always dies, though its roots may send out young shoots. The plants are natives of America, but they are entirely wanting in Chili. The juice of this plant just before flowering is used in America for the manufacture of an intoxicating drink, etc., a very different effect from what is produced from the juice of the leaves of the true aloe.

The true aloe is a very different plant botanically. I have just mentioned that it belongs to the *Liliaceæ*. The aloes are succulent plants, with fleshy persistent leaves, usually prickly at the margin. Some are stemless, others have stems varying from a few inches to 50 or 60 feet, and, it is said, as much as 30 feet in circumference. We are told by Humboldt in his 'Views of Nature' that a plant of *Aloe dichotoma*, Linn., has been found in Africa, with a stem 4 feet in thickness, 20 feet high and a crown measuring 426 feet round. The flowers of the aloe are showy and generally yellow or reddish. The plant flowers freely and frequently, and does not die after flowering, and so is different in many respects from the agave. They are natives of Africa and the adjacent islands, and grow generally in arid sunny places, chiefly in southern and eastern Africa. They are however naturalized in the south of Europe, and in the East and West Indies. It is probable that from most plants of the genus *Aloe* aloes may be obtained, and certain it is that many species contribute to the supply of aloes. As it is no part of my present purpose to describe the varieties of aloes met with in commerce, so I shall not attempt to discuss the question what species yield medicinal aloes. I mean to confine my attention to the different kinds of aloes officinal in the B.P. Medicinal aloes is got from the leaves of the plants.

Aloes is defined in the B. P. as the inspissated juice of the leaves of the aloe. As seen in the shops it occurs in reddish-brown masses, breaks with a peculiar fracture, and has a taste and odour peculiar to itself. The juice is contained in peculiar cells within the leaves, and exudes spontaneously when the leaf is cut transversely.

Only two kinds of aloes are officinal in Britain, Barbadoes and Socotrine aloes. Besides these we meet with Hepatic aloes,—so called because of its resemblance or supposed resemblance to liver,—which comes to Europe by way of Bombay, and is generally supposed to be an inferior kind of Socotrine aloes. We have also Cape aloes from the Cape of Good Hope. Another kind lately introduced into European commerce is Natal aloes, also from South Africa.

I wish now to say a few words regarding the two sanctioned in the B. P.—First, *Aloe Barbadensis.*—This is the inspissated juice of the leaves of *Aloe vulgaris*, imported from Barbadoes. It is described in the B.P. thus:—"In yellowish-brown, or dark-brown opaque masses; breaks with a dull conchoidal fracture; has a bitter, nauseous taste, and a strong, disagreeable odour; and is usually imported in gourds."

The *Aloe vulgaris* has a short, woody cylindrical stem, and curved fleshy glaucous-green and slightly mottled lanceolate leaves, armed with hard distant reddish spines. The scape is *branched*, flowers are yellow. It grows in the East Indies, south of Europe, and in Barbadoes, and hence the name Barbadoes aloes. Some difference of opinion exists as to whether or not the aloe is indigenous to that island. It is perfectly naturalized, but was probably introduced from Africa. It is now regularly cultivated in Barbadoes. Nearly the whole of this island is under cultivation of some kind or other. In the work recently published by Flückiger and Hanbury there is an excellent account of the cultivation of Barbadoes aloes and of its mode of preparation. We are there told that the plants are set 6 inches apart, in rows which are 1 to $1\frac{1}{2}$ feet asunder. The plants are all dwarf, and all above one year old bear flowers. The leaves are 1 to 2 feet long. They are cut annually, but the plant lives for several years. The cutting takes place in March and April, and is performed in the heat of the day. The leaves are cut close to the plant and quickly placed in V-shaped vessels, and the juice allowed to exude spontaneously. In this way the best aloes is obtained. Sometimes the leaves are boiled, but then an inferior kind is produced, owing to impurities being extracted in the process.

Aloe Socotrina is described in the B. P. as the inspissated juice of one or more undetermined species of aloe produced chiefly in Socotra, and shipped to Europe by way of Bombay. This variety occurs in reddish-brown masses, opaque or translucent at the edges, breaks with an irregular, or smooth resinous fracture, has a bitter taste, and a strong but fragrant odour. This kind receives its name from the island of Socotra, at the mouth of the Arabian Gulf, off the east coast of Africa. It is probably produced in great part from the *Aloe Socotrina*, which grows in great abundance in the island.

The *Aloe Socotrina* differs from the *Aloe vulgaris* in having a stem $1\frac{1}{2}$ feet or more high, naked below, sometimes branched, leaves amplexicaul, curved in at the top, and marked with numerous small white marginal serratures. The raceme is *unbranched*. Flowers scarlet at the base, pale in the middle, and green at the point.

I shall now say a few words regarding the substance known in medicine as aloes. I have just stated that it is the inspissated juice of the leaves of certain species of aloe. It flows from the leaves in a liquid state, at first clear, but soon darkens by exposure to the air. In the heat of the sun it gradually concretes into the solid substance so familiar to us all. Aloes has been carefully analysed by several eminent chemists. The three most important constituents of aloes are:—

1. A volatile oil—which was first discovered by the Messrs. Smith of Edinburgh, and was by them exhibited at the Vienna Exhibition in 1873, which sample I was privileged to see some time ago. This oil exists in very small quantity in aloes—only about one ounce being obtained by the Messrs. Smith from the distillation of 400 lbs. of aloes. This oil is a pale yellow mobile liquid—sp. gr., 0·863, and boils at 266° or 271° C. To the presence of this oil is due the odour of aloes. This oil has a resemblance in taste and smell to oil of peppermint.

2. *Aloin.*—This is the most important constituent of aloes. It occurs in beautiful crystals which are supposed to be a hydride of the amorphous aloin.

This substance was discovered by the Messrs. Smith in 1851. The importance of this addition to our knowledge of the chemistry of aloes cannot be overstated, inasmuch as it has been clearly proved that this is the active principle of the drug. Aloin constitutes about twenty-five per cent. of aloes. Some chemists are of opinion that aloin from the various kinds of aloes is slightly different in regard to solubility, boiling point, and form of crystals, etc. The latest theory regarding aloin is so very ingenious that I cannot refrain from mentioning it,—namely "That the aloin got from the various kinds of aloes forms a homologous series in which the difference is CH_2. According to this theory—

The Aloin from Socotrine Aloes is $C_{15}H_{16}O_7$.
„ Natal „ $C_{16}H_{18}O_7$.
„ Barbadoes „ $C_{17}H_{20}O_7$.

This is so very beautiful that we wish it could be established. It requires, however, to be proved. Be that as it may, aloin is an oxidized hydrocarbon. It gives no ash when burned.

3. *Resin of Aloes.*—The substance which deposits from a decoction of aloes as it cools is usually denominated *resin of aloes.* This substance often contains a variable amount of aloin, owing to the extreme difficulty of entirely exhausting the aloes of aloin.

To obtain this resin in the purest possible state, the following plan was adopted by the Messrs. Smith. They took some resin prepared in the ordinary way, and which had been subjected to four additional washings, and dissolved it in rectified spirit, which dissolves the aloin as well as the resin, and to this was added boiling water, and the whole agitated so as to form a sort of emulsion. From this the resin separated in a very fine state, and I believe as free from aloin as any resin could well be.

Very absurd notions regarding this resin are held by Dr. Tilden and others as to its physiological action, of which I have some important communications to make this evening, and in almost all works on materia medica it is spoken of as a "modified aloin" as aloin oxidized or otherwise changed by exposure to the air. Chemically it is essentially different from *aloin*, and physiologically it bears no resemblance to it whatever; were it changed aloin it would produce no ash when burned—and, moreover we would expect it to have the physiological action of aloin, which changed aloin undoubtedly has, as I shall presently show.

The Messrs. Smith were kind enough to furnish me with the following particulars regarding experiments on this resin of aloes—I mean the *resin* prepared in the manner just described:—

Eight hundred and eighty-three grains of this *resin* were thoroughly dried; of this quantity 753 grains were found to be soluble in rectified spirit, and 130 grains were insoluble.

The *soluble resin* gave 1 per cent. of ash when burned. The insoluble resin gave 23 per cent. of ash. These experiments alone are sufficient to disprove the common assertion that the resin of aloes is modified aloin.

These are the *three* principal ingredients of aloes.

In regard to the preparations of aloes I shall not say much.

From Barbadoes aloes we have *seven* preparations, and from Socotrine aloes *eleven* preparations.

The dose of aloes is 2 to 6 grains, and it is best given in pill.

Aloes in small doses is a tonic. It assists digestion. It gives tones to muscular tissue, and is thought, and I believe correctly, to exert a special influence on the liver.

In larger doses, it is a purgative. It acts specially on the large intestine. It increases the intestinal secretion, and also the peristaltic motion of the bowels. It also stimulates the uterus, and hence is useful in certain sluggish states of that organ. The sulphate of iron and other substances increase its purgative action.

It is generally said to cause griping, but I believe not nearly so much as many suppose. In olden times the *resin* was looked upon as the cause of the griping. This, however, has been clearly disproved. When aloes gripes, it will probably be found that this untoward result is mainly due to some impurity in the drug.

Having thus briefly directed attention to the natural history, chemistry, pharmacy, and therapeutics of aloes, I wish to submit the results of some original researches into "changed aloin" and the "resin of aloes," and though from the very nature of the investigation I shall have much to do with figures, yet I shall endeavour so to deal with those figures that they shall not be altogether uninteresting to those whom I have the honour of addressing.

Although aloes has been used in medicine for more than 2000 years, it was not till 1851 that the Messrs. Smith of this city discovered in aloes a crystalline principle to which they gave the name *aloin*, on account of its being supposed by them to be the active principle of the drug. After this important discovery of aloin much difference of opinion existed regarding its physiological action. So late as 1870, we find Dr. Tilden, of London, maintaining that the purgative property of aloes is not due to aloin, that the active constituent of aloes is still unknown and that in all probability it is due to the resin of aloes. Even in the present day, there appear to be doubts in the minds of some regarding the activity of aloin, and in a recently published work on materia medica, a work emanating from the Edinburgh School of Medicine,* there is not one word regarding the action of aloin.

Notwithstanding these statements, it has been clearly demonstrated by various experimenters, and confirmed by clinical observation, that aloin is an active aperient and is sufficient to account for the purgative property of aloes.

It was no part of my intention in the following experiments to determine the action of aloin, but to investigate the properties of "changed aloin," and to determine the action of the "resin" of aloes.

In 1872, the Messrs. Smith, of this city, when preparing a specimen of *aloin* for the Vienna Exhibition, took four ounces of aloin and dissolved it in order to recrystallization, that they might obtain very pure crystals of aloin. From this solution two ounces of very beautiful crystals were obtained, and the residue was set aside for some months. To this, distilled water was added, and after eight months a dark coloured substance had formed, easily reduced to a fine powder, and to which they have given the name "changed aloin." It is undoubtedly aloin which has undergone some change by exposure to the air, probably a species of oxidation.

They were naturally anxious to ascertain if this substance possessed the activity of aloin. They applied to me to investigate this question, which I accordingly did, and found that this aloin which had undergone some chemical change still possessed its physiological action.

My experiments were performed on healthy young rabbits. I had prepared a cage in such a manner that I could easily measure the urine and weigh the fæces daily. The first six days I fed the rabbit daily, at a fixed hour, with ten ounces of carrot, and each day measured the urine and weighed the fæces. The next six days I injected daily one grain of this changed aloin under the skin of the rabbit. The experiments were made at a fixed hour, and were generally performed on the sides of the animal.

Table I.

First six days. No injection. Ten ounces of carrot daily:—

1st day.	Urine,	56	fluid drachms;	Fæces,	Nothing.
2nd day.	„	74	„	„	„
3rd day.	„	68	„	„	„
4th day.	„	53	„	„	„
5th day.	„	60	„	„	Traces.
6th day.	„	64	„	„	„
Average.	„	62·5	„	„	0

Second six days. One grain in solution of changed

* 'Materia Medica,' by Dr. Scoresby Jackson, 3rd Ed. (Dr. Macdonald), 1875.

aloin injected subcutaneously daily—and ten ounces of carrot each day as formerly :—

TABLE II.

1st day.	Urine,	48 fluid drachms ;	Fæces,	59 grains.
2nd day.	„	60 „	„	121 „
3rd day.	„	68 „	„	184 „
4th day.	„	60 „	„	38 „
5th day.	„	64 „	„	10 „
6th day.	„	64 „	„	8 „
Average.	„	60·7 „	„	70 „

On comparing carefully these two sets of experiments, we find some remarkable facts established. Ten ounces of carrot formed scarcely a sufficient diet for the animal, but this in no way invalidates the results, seeing that the same amount was given during the whole twelve days.

During the first six days, the urine varied from 53 fluid drachms to 74 fluid drachms, average, 62·5 fluid drachms daily. During the next six days with the same quantity of food and the injection of one grain of changed aloin daily, the amount of urine varied from 48 fluid drachms to 68 fluid drachms, average, 60·7 fluid drachms daily, being nearly the same as in the first six days.

With regard to the *fæces* the results were very different. During the first six days there were no fæces, or only traces on the fifth and sixth days. During the next six days, when one grain of changed aloin was injected subcutaneously daily, the fæces varied from 8 grains to 184 grains, average 70 grains daily. The first day after the injection there were 59 grains of fæces, the second day 121 grains, the third day 184 grains, and on the three following days they gradually diminished to 8 grains on the last day. There was a marked effect the very first day after the injection. The amount increased gradually for three days, and then diminished for the next three days. This fact is easily accounted for when we bear in mind that having once emptied the bowels by means of aloin, and the food not being increased, we could not expect the same amount of fæces from the purgative action of the drug. Nevertheless, the results were so marked, and followed so soon after the administration of the drug, that there is no resisting the conclusion that this "changed aloin" is a certain and an efficient aperient, and possesses the physiological action of aloin. Being anxious to observe its action on man, I had pills specially prepared with extract of gentian, and containing no ingredient except the "changed aloin" and gentian. These pills contained from 1 to 2 grains of this "changed aloin." I administered these pills to a number of individuals, and in very various circumstances, and invariably found them to act as an aperient, and in no case was there any griping. I gave it in several cases of habitual constipation, occurring in persons of a sedentary habit (1 or 2 grains daily), and found it answer remarkably well. I also administered it to pregnant females during the latter weeks of pregnancy, and succeeded in removing the constipation so common in females shortly before confinement. I also gave it on several occasions to females after delivery, and invariably found it a mild aperient, and in no case did any bad effect follow its administration. It will thus be observed that clinical observation fully corroborates the conclusion drawn from experiments on the lower animals that this *changed aloin* possessed the physiological action of the active principles of aloes.

These experiments and clinical observations are interesting and of considerable importance, inasmuch as they prove that aloin, which undoubtedly is the active principle of aloes, may, by exposure to the air, undergo considerable chemical change without losing its physiological action.

I come now to consider the action of the so-called "*resin of aloes*," a substance about which there is much diversity of opinion regarding its chemical composition, and whose physiological action has hitherto never been properly investigated. The resin of aloes generally contains a variable amount of aloin on account of the extreme difficulty of thoroughly exhausting the aloes of its aloin. This fact undoubtedly has led some observers to the conclusion that the resin of aloes possessed purgative properties. With the view of determining this important question, I made the following experiments. The resin of aloes was carefully prepared for me by the Messrs. Smith, of this city.

My experiments were performed on healthy young rabbits :—For six days I gave a rabbit daily 14 ounces of carrot, feeding it always at the same hour. The urine and fæces were carefully collected, and their amount duly ascertained.

The following table represents the results :—

TABLE III.

1st day.	Urine,	86 fluid drachms ;	Fæces,	209 grains.
2nd day.	„	82 „	„	167 „
3rd day.	„	73 „	„	3 „
4th day.	„	78 „	„	341 „
5th day.	„	82 „	„	0 „
6th day.	„	64 „	„	70 „
Average.	„	77·5 „	„	136·6 „

During the next six days I gave the rabbit daily, at the same hour, 14 ounces of carrot, and injected subcutaneously 1 grain of the "resin of aloes" in solution, with the following results :—

TABLE IV.

1st day.	Urine,	96 fluid drachms ;	Fæces,	6 grains.
2nd day.	„	60 „	„	83 „
3rd day.	„	76 „	„	213 „
4th day.	„	84 „	„	100 „
5th day.	„	60 „	„	290 „
6th day.	„	100 „	„	105 „
Average.	„	79·3 „	„	132·8 „

On comparing these two sets of results we find that the urine was slightly increased on the average, but not to such an extent as warrants the conclusion that the resin of aloes is diuretic. With regard to the fæces it will be observed that the amount varied very much on different days; from nothing to 341 grains during the six days when no injection was given, and from 6 grains to 290 grains during the time of the injection. Nevertheless, the daily average was nearly the same in both sets of experiments, being 136·6 grains when no injection was used, and 132·8 when 1 grain of the resin of aloes was injected daily. In this case the fæces were slightly diminished during the time of the injection, clearly proving that 1 grain of the resin of aloes failed to produce any purgative action.

I was anxious to ascertain if larger doses of the resin of aloes would produce any different results, and accordingly I injected subcutaneously 2 grains of the resin of aloes in solution, and fed the animal as before with 14 ounces of carrot daily.

The following are the results :—

TABLE V.

1st day,	Urine,	72 fluid drachms ;	Fæces,	202 grains.
2nd day.	„	80 „	„	16 „
3rd day.	„	76 „	„	200 „
4th day.	„	78 „	„	190 „
5th day.	„	72 „	„	771 „
6th day.	„	70 „	„	460 „
Average.	„	74·6 „	„	306·5 „

It will be seen at once that the urine remained much the same throughout the whole of these experiments, but not so with the fæces. During the six days that 2 grains of the resin of aloes were injected daily, the fæces varied from 16 grains to 771 grains—average 306·5 grains, whilst the average amounted to 136·6 grains when no injection was used, and to 132·8 grains when only 1 grain of resin of aloes was injected. On examining carefully the results of the last six days, it will be observed that the large daily average is due entirely to the large amount of fæces obtained on the fifth and sixth days; but on five of the six days was the daily average about the average when no injection was used, and when one grain was injected daily. There can be no doubt that this resin of aloes which I used in doses of two grains acted as a purgative, though in doses of one grain it failed to produce any purgative action. I may mention that I had pills prepared with extract of gentian, each pill containing 2 grains of the resin of aloes, and found that four of these pills or more produced three or four watery stools—again confirming by clinical observation what I had found as the result of experiments on the lower animals. On communicating the results of my experiments to the Messrs. Smith, they suggested that it was possible that the resin of aloes which they gave me might have contained a small quantity of aloin, and that the purgative effect obtained might be due to this aloin. The resin of aloes with which I was experimenting was very carefully prepared from a solution of aloes in boiling water and had received four additional washings. The Messrs. Smith informed me that resin of aloes prepared even with such care, might contain aloin owing to the extreme difficulty of entirely exhausting aloes of its active principles. They accordingly took a quantity of the resin of aloes prepared in the manner above described, and dissolved it in rectified spirit, to which solution they added boiling water and then agitated the mixture from which the resin of aloes afterwards separated in a fine state. The resin so prepared might be regarded as pure resin, and as free from aloin as any resin could be.

The following experiments were performed with this resin prepared in the manner just described, and were conducted in much the same way as I conducted the other experiments.

A healthy young rabbit, weighing two pounds and seven ounces, was fed daily on 14 ounces of carrot for six days, and the urine was carefully measured and the fæces weighed every day.

The following table represents the results obtained:—

Table VI.

1st day.	Urine,	56	fluid drachms;	Fæces,	4	grains.
2nd day.	„	76	„	„	30	„
3rd day.	„	88	„	„	2	„
4th day.	„	80	„	„	203	„
5th day.	„	64	„	„	67	„
6th day.	„	64	„	„	57	„
Average.	„	71·3	„	„	60·5	„

The next six days I injected daily two grains of resin of aloes subcutaneously. (The first two injections were with the first resin I used, the others with the new resin prepared with extra care.)

The following were the results:—

Table VII.

1st day.	Urine,	68	fluid drachms;	Fæces,	127	grains.
2nd day.	„	56	„	„	192	„
3rd day.	„	56	„	„	87	„
4th day.	„	64	„	„	30	„
5th day.	„	48	„	„	3	„
6th day.	„	66	„	„	232	„
Average.	„	59·6	„	„	111·8	„

On comparing these two sets of experiments it will be seen that the urine was slightly diminished, but the fæces were considerably increased. The average in the one case without any injection being 60·5 grains daily, whereas the average when two grains of the resin of aloes were injected amounted to 111·8 grains daily. It must be remembered that the first two injections were with the resin I formerly used, and which was decidedly purgative, and that the average for these two days was 159·5 grains daily. The daily average for the other four days was only 88 grains.

The next six days I fed the rabbit on 11 ounces of carrot daily, as it was found that 14 ounces were too much. No injection was given.

The following are the results:—

Table VIII.

1st day.	Urine,	36	fluid drachms;	Fæces,	2	grains.
2nd day.	„	76	„	„	81	„
3rd day.	„	64	„	„	198	„
4th day.	„	52	„	„	420	„
5th day.	„	56	„	„	0	„
6th day.	„	68	„	„	120	„
Average	„	54·6	„	„	136·8	„

The next six days I fed the rabbit also on 11 ounces of carrot daily, and injected each day 2 grains of the new resin of aloes which was so carefully prepared.

The following table contains the results:—

Table IX.

1st day.	Urine,	44	fluid drachms;	Fæces,	154	grains.
2nd day.	„	56	„	„	197	„
3rd day.	„	64	„	„	94	„
4th day.	„	80	„	„	50	„
5th day.	„	52	„	„	272	„
6th day.	„	60	„	„	108	„
Average.	„	59·3	„	„	145·8	„

On comparing these last two tables it will be observed that the urine is slightly increased, but only to a limited extent. The daily average of the fæces was increased by 9 grains, but this is so small an increase that we cannot draw from it any conclusion in regard to the purgative property of the resin of aloes. The largest amount of fæces obtained during one day when the injection was used was 272 grains. Whereas, on the other hand, 420 grains were obtained one day when no injection was used. The daily average increased gradually during each period of six days, without reference to the injection of the resin of aloes. The rabbit increased in weight from two pounds and seven ounces to two pounds and eleven and a half ounces. In twenty-four days it increased four and a half ounces in weight. On a careful comparison of the whole of these experiments with the resin of aloes it will be observed that no appreciable effect was produced even by the subcutaneous injection of two grains of this resin.

During the first six days when no injection was used, the daily average amount of fæces was 60·5 grains; during the second six days it was 111·8 grains with 2 grains of resin of aloes injected daily; during the third six days, with no injection, the daily average was 136·8 grains; and during the last six days, with 2 grains of resin of aloes injected daily, the average was 145·8 grains. There is but one conclusion to be drawn from these experiments, namely, that the resin of aloes is not purgative, and cannot be the active principle of the drug.

I had some of this resin made into pills with extract of gentian, each pill containing 2 grains of resin, and found that six such pills taken within one day failed to produce any effect whatever. I thus found that my clinical experience fully confirmed the conclusion arrived at from my experiments on the lower animals. Dr. Farre, of London, gave to patients doses of three grains of resin, and said that he found it almost inert, and that it seldom produced any evacuation. He, however, holds the rather doubtful conclusion that though it is inert when separated, it is probably active when combined. This conclusion is more than doubtful. In those cases where three grains produced evacuation, the activity was most likely due to the resin containing a small quantity of aloin. As previously stated, it is exceedingly difficult to exhaust the aloes entirely of its aloin; and in proportion as it contains any of this substance, so will it prove more or less active. But when the resin is prepared with the care that the last sample was with which I experimented, it will prove altogether inert. Similar results were obtained by Dr. Garrod, although it is evident from his experiments that the resin was not always free from aloin. He says the *extract* is far more active as a purgative than the resin, and admits that the resin often proved almost inert. I believe that had the resin with which he experimented been perfectly exhausted of aloin, it would have been always inert. Nevertheless the experiments of Dr. Farre and Dr. Garrod are exceedingly valuable and very interesting, and tend very much to show that the resin is an inert substance.

I think I have thus far established the point that the opinion of Dr. Tilden regarding the activity of the resin of aloes is altogether untenable. It is contradicted by the experience of the observers just named, and my experiments both on man and on the lower animals are conclusive on the point.

In speaking of the action of the resin of aloes, I must not omit to mention that to this resin is generally ascribed the griping property of aloes. My own opinion is that aloes does not gripe nearly so much as writers on materia medica would lead us to believe. When it does gripe, it is probably on account of some impurity in the drug, and certainly it cannot by any possibility be due to the resin. It was with the view of determining this question that the experiments of Dr. Farre and Dr. Garrod were performed, and they both came to the same conclusion that the resin was not the cause of the griping. My experience fully coincided with theirs. I gave it to a large number of patients and in very different circumstances, in doses varying from four to twelve grains, and in no single instance did it produce griping. It thus appears that the resin is not only inert, but is also a very harmless substance.

These experiments are also interesting as bearing on the chemical constitution of the resin of aloes. They are entirely at variance with the generally received opinion that this *resin* is "modified aloin." I have clearly demonstrated that "changed aloin," which very much resembles *resin* in appearance, is an active aperient, possessing all the activity of aloin itself, whereas the *true resin* is altogether inert.

The following may be regarded as conclusions fairly deducible from the foregoing experiments:—

1. Aloin may by exposure to the air undergo considerable chemical change without losing its physiological action as an active aperient.

2. That the *resin* of aloes, when thoroughly exhausted of aloin, possesses no purgative properties, and therefore cannot be the active principle of aloes.

3. That the resin of aloes is not the cause of the griping which sometimes follows the administration of the drug.

4. That aloin is an active aperient, and is in all likelihood *the active* principle of aloes.

When these experiments are viewed in connection with the researches of numerous experimenters in regard to the activity of aloin, we are forced to the conclusion that aloin is the only active principle contained in aloes, and is sufficient to account for all the purgative properties of that medicine. And that being the case, I cannot conclude without expressing a regret that in the Addendum to the British Pharmacopœia of 1867, published in 1874, no mention is made of aloin. It ought to find a place amongst the medicines recognized in the B.P. It possesses the following advantages over the crude drug:—

1. Being uniform in strength, its dose can be more accurately determined.

2. Its dose being only gr. ss. to gr. j., it can easily be introduced into tonic pills without making these pills too large.

3. By using the active principle we get rid of all impurities which are so apt to cause griping.

Its uniformity in strength, the smallness of its dose, and the certainty of its action should commend it to the favourable consideration of all medical practitioners.

The following pill I believe to be superior to the Pil. Ferri et Aloes of the B.P.

℞.	Aloin	gr. ss.
	Ferri Sulph. Exsic.	gr. jss.
	Extract. Nucis Vom.	gr. ss.
	Extract. Belladon.	gr. ss.

Fiat pil.
One or two pills daily.

This I have found an excellent pill for the constipation so common in females of a sedentary habit.

But I must now hasten to a close. You perceive that I have been endeavouring to solve some of the questions about which there was some difference of opinion regarding a drug known to medical men for more than 2000 years, and used in every country where the healing art is known. In my researches into the action of changed aloin and the *resin* of aloes, my sole object has been to ascertain the truth regarding them, and as I undertook these investigations at the recommendation of a distinguished pharmaceutical chemist of Edinburgh, and one whose researches into the chemistry of aloes are second to none in the kingdom (I refer to Mr. T. Smith, of T. and H. Smith of this city), and if the researches should prove of any value, and tend in any degree to add to our knowledge of the action of the constituents of aloes, I shall ever regard it as a high honour to me that the results of my experiments should have been first communicated to the North British Branch of the Pharmaceutical Society—a Society to which I take this opportunity of tendering my sincere thanks for their kindness to me as a Lecturer on Materia Medica in the Edinburgh School of Medicine.

CITRATE OF IRON AND BISMUTH.*

BY C. RICE.

Being requested some years ago to devise a liquid preparation containing bismuth and iron (at that time intended for use in some other complaints besides dyspepsia), I finally, after various trials, adopted the following formula, which I have followed ever since:—

Take of citrate of bismuth, ammonio-citrate of iron, each 320 grs.; water of ammonia, water, each a sufficient quantity.

With 4 oz. of water rub the citrate of bismuth into a smooth paste; gradually add water of ammonia until solution has taken place, being very careful not to have an excess of ammonia. Now add the ammonio-citrate of iron and some more water; dissolve, filter, and wash the filter with enough water to make the solution measure 1 pint.

This solution if intended to be long kept may be partly made up with glycerine, although I cannot speak from experience whether it is so well borne by the stomach. A more useful addition, however, is good sherry wine, of which there may be used 10 fluid oz. (or perhaps more), in place of so much water.

The above solution is prescribed under the name of liquor ferri et bismuthi citratis, and contains in 1 fluid drachm 2½ grains each of citrate of bismuth and ammonio-citrate of iron. The dose is from 1 to 2 fluid drachms, half an hour before meals, or, when required, after meals.

It is, of course, no true double salt, chemically speaking, but only a mixture of ammonio-citrate of bismuth and ammonio-citrate of iron; and although a true double salt containing those elements might perhaps be prepared I doubt whether it could have any better effects.

The solution may also be prepared of a concentrated state, and spread upon plates of glass to dry, yielding exceedingly handsome scales of a golden-brown colour, which must be protected from the light, and 5 grains of which are equal to 1 fluid drachm of the solution.

---

* From the *Druggists' Circular.*

The Pharmaceutical Journal.

SATURDAY, APRIL 17, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE GLASGOW MEMORIAL.

AT the special request of the PRESIDENT and SECRETARY of the Glasgow Chemists and Druggists' Association we call the attention of our readers to an explanatory note those gentlemen have forwarded for publication, which will be found at p. 843 of the present number of the Journal.

We must confess to being under some difficulty in complying with their desire that we should also make some further reference to this note, since we fail to perceive in it anything calculated very materially to modify the opinions we have already expressed.

In regard to the surprise we expressed at the small number attending the meeting at which the memorial was adopted and directed to be sent to the Council of the Pharmaceutical Society we may remark that we were guided by the statement of Mr. FRAZER at the Council meeting. It now appears that though this seems to have been the only meeting of which Mr. FRAZER was cognizant, the draft memorial had already been adopted at a previous meeting of the trade, numbering about sixty town and country members, and that many others who could not attend that meeting were in favour of of the memorial. While accepting this explanation as in some degree removing the ground for the impression we were at first led to form, we cannot but declare that the circumstance of there being so many who sympathize with the memorial seems to be an additional reason for regret. For the explanatory note furnishes nothing in the shape of fact or argument in support of the grave allegations of the memorial, and since we regard those allegations as being entirely fallacious, we can only deplore the fact of their being so much more generally entertained by the chemists and druggists of the West of Scotland than we had supposed to be the case.

As to the disclaimer of any intention on the part of the memorialists to cast any imputation on the Board of Examiners in Scotland, we gladly accept it, since it is unquestionably a matter of great importance, especially at the present moment, that nothing should be done to lessen in any degree the respect in which the Examining bodies of the Society should be held. But while giving the memorialists all credit for their good intentions, it is to the purport and effect of their complaints that attention must be directed in judging of such a document as the Glasgow memorial. In that respect we do not hesitate to say that the statements contained in the memorial do cast discredit on the system of Examination, inasmuch as it is represented as being in certain particulars inimical to the future progress of the trade, and as having estranged young men from becoming apprentices or students of the business.

Regarding the memorial merely from this point of view we thoroughly concur with Messrs. CURRIE and FAIRLIE in the hope that, as a result of the motion Mr. FRAZER has given notice of, the memorial will receive thorough consideration when it again comes before the Council. Whatever opinion may be entertained as to its merits, it is certainly desirable that the alleged evils attending the present system of examinations should be discussed and inquired into in such a manner as to dispose of them finally. The revival of this subject after the opportunities that have lately been afforded for communication and consultation between the Examining Boards of Scotland and England and the Council of the Society, and after the satisfactory conclusions we were disposed to believe had resulted from these measures, seems to show that there is still some unexplained cause of discontent. It would be well for the interest of all concerned if that could be discovered and remedied.

We are glad to find some evidence afforded by the letters of other correspondents on this subject that these opinions are not general in Scotland, and we are glad to find that the writer of one of the letters which we publish this week promises to follow up the subject. We are especially glad to learn that he will deal with the alleged scarcity of assistants, for it is this point which, so far as we can gather, seems to lie at the root of that vague dissatisfaction indicated by the Glasgow memorial as prevailing in the minds of some members of the trade in Scotland. Upon the principle that a disease may be successfully treated when its cause has been discovered, we hopefully look forward to the elucidation of the question why there is such reluctance to take up the career of a chemist and druggist in Scotland.

Having said thus much on the general aspects of the matter we shall abstain from any further comment on the memorial and its objects until such time as we may be in possession of a more adequate collection of facts. But at the same time we must take this opportunity of remarking that we cannot admit the justice of the objection raised by Mr. CURRIE and Mr. FAIRLIE to our having taken up the memorial in the editorial columns of the Journal.

THE SALE OF VERMIN POWDERS.

LATTERLY we have heard much less of poisoning with vermin killers containing such poisons as strychnine than used to be the case, and this may, we believe, be attributed to the fact that greater precautions have been taken in the sale of these preparations since they were placed upon the same footing as the poisons they contain. But it would seem that something further still remains to be done in order to protect vendors of these preparations from inconvenience in the event of accident or misuse.

In illustration of this we refer to the report, at p. 840, of the prosecution of a firm of chemists and druggists for having unlawfully sold a packet of Battle's vermin killer to a person not known to them. The evidence of the man who purchased the vermin killer and attempted to poison himself with it was to the effect that he had been drinking heavily all the previous week, and at the time he bought the poison he was so drunk that he did not know anything about it. The assistant who supplied him with the vermin killer, however, stated that the man appeared to him to be sober when he was in the shop. No great importance is, we believe, to be attached to this conflict of testimony, especially as the poison was sold on a Saturday evening, when there may have been a press of business in the shop. It is also quite possible that the man may have been drunk at the time without it being noticeable.

For the defence it was urged that the assistant knew the man as a frequent customer, and as being in the employ of a manufacturer in the town, and hence it was contended that there was no infringement of the Act relating to the Sale of Poisons. However, the magistrates held it was indispensable to take the address as well as the name of any purchaser of poison so that his whereabouts could be found in the event of his being wanted. The book used for the purpose of registering sales of poison, however, did not provide for the address of the purchaser to be entered, and if, as we presume, this book was one with printed forms it would be desirable at once to have it replaced by one properly prepared in accordance with the provisions of the Act.

As remarked by one of the magistrates, the omission was a trifling one, but as it might have resulted in serious consequences there was no alternative but to convict, and the seller of the poison was therefore fined £1 with costs.

We think it desirable to call the attention of our readers to this case as showing the advantage they may derive from careful compliance with the provisions of the Act. If the simple formality of writing down the purchaser's address in the poison sale register had been observed, the seller of the poison would, in this case, have been held blameless in the eye of the law, and even if he had been summoned before the magistrates in reference to the attempted suicide, the result would have been to show that he was in no way censurable, and in so far it would have been beneficial to him rather than otherwise.

THE ANNUAL DINNER.

A MEETING was held at 17, Bloomsbury Square, on Wednesday last, to discuss the preliminaries of the fourth Annual Dinner of the Members of the Pharmaceutical Society and their friends.

It was decided to hold the Dinner at WILLIS'S Rooms, King Street, St. James's, and the following gentlemen were appointed a committee to carry out the arrangements:—

The PRESIDENT.	FREDERICK BARRON.
The VICE-PRESIDENT.	A. F. HASELDEN.
The TREASURER.	Dr. PAUL.
Professor ATTFIELD.	G. W. SANDFORD.
W. R. BARKER.	

Messrs. RICHARD BREMRIDGE and MICHAEL CARTEIGHE, who have again undertaken the duties of Honorary Secretaries, will be glad to receive, on or before Wednesday next, the names of gentlemen who are desirous of acting as Stewards, as it will be necessary to publish the list forthwith.

THE MEDICINE STAMP TAX IN THE UNITED STATES.

LITTLE more than a year since* we referred in these columns to the troubles of our American brethren in respect to the very elastic application of the Medicine Stamp Act of that country to all medicinal preparations kept in packages ready for sale. We learn from the *American Journal of Pharmacy* for March, that by an Act to Amend the Existing Customs and Internal Revenue Laws, which has received the official sanction of the PRESIDENT, the conditions under which medicinal preparations are or are not liable to stamp duty are more clearly defined; and so far the pharmacist has received a boon. It appears that under the provisions of the new law, no medicine which is packed anticipatory of sale, if it be prepared in accordance with a formula published in any standard Dispensatory or Pharmacopœia in common use by physicians and apothecaries, or in any pharmaceutical journal issued by an incorporated college of pharmacy, is to be liable to duty, provided that a distinct reference to the formula and where it is to be found be printed on the label attached to the article, and no proprietary interest therein be claimed. In other cases, no stamp is to be required if the formula of the preparation be printed on the article and no proprietorship be claimed.

THE EBERT PRIZE.

IT will be remembered that on the occasion of retiring from the Presidency of the American Pharmaceutical Association in 1873, Professor ALBERT E. EBERT, of Chicago, devoted a sum of five hundred dollars to the establishment of an annual prize for the best essay or written contribution containing an

* Vol. iv., p. 517.

original investigation of a medicinal substance or information respecting improved methods for the preparation of chemical or pharmaceutical products. The committee appointed to award the prize has recently made its report upon the essays presented at the last meeting of the Association. Three papers were selected for special consideration, viz., 'On Colchicia,' by Mr. EBERBACH, 'On Iron by Hydrogen,' by Mr. J. CREUSE, and 'The Active Principles of the Officinal Veratrums,' by Mr. C. L. MITCHELL. The Committee recommends that the EBERT Prize for 1874 be given to Mr. C. L. MITCHELL, the author of the latter paper, which is now in course of publication in this Journal.

CINCHONA IN MADEIRA.

A LETTER received by Dr. HOOKER from Madeira seems to show, according to the *Gardener's Chronicle*, that the climate of that island is especially suited to the growth of *Cinchona succirubra*, since a specimen planted two years and a half ago in a garden at an elevation of 500 feet above the sea is now nearly twenty feet high, and blossoms freely. *C. Condaminea*, however, does not appear to succeed so well; some plants sent from Kew six years ago have been increased by cuttings, but these are reported to be making but little progress.

A MEETING of the London Local Committee of the British Pharmaceutical Conference was held on Wednesday last at 17, Bloomsbury Square. The Honorary Local Secretary, Mr. CARTEIGHE, reported that the contributions to the Fund subscribed by the London members and their friends to defray the expense of entertaining the visitors from the country to the Annual General Meeting in August last, had amounted to £650 18*s.* 6*d.* Of this sum £584 3*s.* 2*d.* had been expended, leaving a balance in hand of £66 15*s.* 4*d.* In accordance with the unanimously expressed wish both of present and absent members of the Committee, it was proposed by Mr. A. C. WOTTON, seconded by Professor ATTFIELD, and resolved that this balance should be presented as a donation to the Benevolent Fund of the Pharmaceutical Society.

AT the Leicestershire Easter Sessions, held on the 5th inst., Mr. JOSEPH YOUNG, Pharmaceutical Chemist, was reappointed Public Analyst for the County. Some opposition was offered to the reappointment by Mr. PELL and Sir HENRY HALFORD, who wished to defer action in this matter until after the Government Bill now before Parliament has passed; but a motion to that effect was lost.

Mr. JAMES DEWAR, Demonstrator of Chemistry in the University of Edinburgh, has been elected to the Jacksonian Chair, at Cambridge.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

A special meeting of the above Society was held in the Architectural Society's room, Gold Street, on March 22, 1875, Jas. Barry, Esq., J.P., in the chair.

The early part of the evening was occupied in looking at some very beautiful stereoscopic views of continental scenery lent by the chairman, and a variety of microscopic objects shown by Messrs. Osborne, Magger, and Druce, including sections of medicinal woods, crystals of the alkaloids, etc. Mr. Camplin exhibited one of Weiss's batteries. Specimens of jaborandi were exhibited by Mr. Wallis, and salicylic acid was also shown. Mr. Druce exhibited a collection of old officinal plants such as dittany of Crete, cydonia, staphisagria, etc., and nearly all the English *Rosaceæ*, and Mr. Dadford lent a large kaleidoscope.

In commencing the business part of the meeting Mr. Hester, the President, alluded to the prosperous state of the Society's finances and said he thought it would be proper, considering they were getting so wealthy, to elect as trustees some principals in the town. After some discussion he formally moved—"That five principals should be elected to administer the affairs of the Association, and when from any cause the number be reduced to three a meeting of the Association should be called to fill up the vacancies."

This motion having been seconded by Mr. Amery, and put to the meeting by the chairman, was carried *nem. con.*

Messrs. Barry, Berry, Bingley, Jeyes, and Magger were then elected as trustees.

Mr. Kemp said that if at any time—and he hoped and thought it would be a far distant time—the Association should come to an end, it would be proper for the members to intimate their desire in what manner the proceeds should be utilized, so he proposed—"That in case the affairs of the Association should ever be wound up, the balance of the effects, after paying all debts, be handed over to the Benevolent Fund of the Pharmaceutical Society."

Mr. Wallis seconded the proposition, and it was after discussion carried unanimously.

The Secretary said that they had received the calendar from the Pharmaceutical Society, and Mr. Barry had kindly offered two volumes of Faraday's 'Researches on Electricity.' After a cordial vote of thanks to Mr. Barry the meeting terminated at an unusually late hour.

It is intended to hold morning botanical classes in May.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Tuesday evening, March 30, a lecture on "Water, its Impurities, and How to Detect Them," was delivered before the members of the above Association, by Mr. J. Young, public analyst to the counties of Leicester, Rutland, and Northampton. In the absence of the President, the chair was taken, at half-past eight o'clock, by Mr. W. B. Clark, who briefly introduced the lecturer.

Mr. Young in his opening remarks dwelt on the importance to pharmaceutical chemists of a practical knowledge of the various methods for determining the purity of water, inasmuch as no question is more frequently referred to them for investigation than the fitness or unfitness of water for potable purposes. He then proceeded to enumerate the impurities usually found in water, and to classify them according to their nature and the sources from which they are derived. The first group consisted of those salts of calcium and magnesium, such as the carbonates, sulphates, chlorides, etc., which are derived from the soil through which the water percolates, and which, according to the quantities present cause it to be more or less hard. The question whether the presence of these salts is a disadvantage was also discussed, and various medical authorities cited, showing that, whilst a small quantity might be beneficial, yet, if the amount exceeds thirty or forty grains in each gallon of water a continued use of such water would be deleterious to health. The soap test proposed by Professor Clark for estimating the comparative hardness of water was then performed and explained, and the audience were instructed how to prepare the standard solutions necessary for its performance. The lecturer then passed on to the second group, which consisted of impurities derived from contact with decaying animal matter, etc. He stated that there are always two substances present in water which is contaminated with organic matter, viz., chlorine and ammonia. With regard to chlorine, he said that though the presence of organic impurity involved that of chlorine, yet the converse was not true, as chlorine is frequently found in water perfectly free from those substances. The presence and relative quantity of chlorine in water might easily be ascertained by the addition of a standard solution of nitrate of silver, until a precipitate ceases to be formed, were it not very difficult, from the opacity of the liquid, to know when to stop. A much more accurate result would be obtained, however, by the addition of a little solution of chromate of potassium previous to the precipitation with nitrate of silver; this causes a deep red precipitate of chromate of silver directly the chlorine has all been neutralized. With regard to ammonia, Mr. Young said, its presence in water proved conclusively that the impurity arose from contact with organic substances, it was, therefore, a much more valuable test of the purity or otherwise of water than the presence or absence of chlorine, the more so, because, by means of the reagents generally employed the presence of an infinitesimally small quantity, such as the millionth of a grain, could be ascertained with certainty. The test usually applied is that discovered by Nessler, viz., the addition to the suspected water of a solution of biniodide of mercury in liq. potassæ or liq. sodæ, the result being that, if ammonia is present, a brown tint is imparted to the liquid, caused by the precipitation of biniodide of mercury. If the animal matter should have been further decomposed in the water so as to form nitrites of potassium, etc., with salts already existing, these might be detected by the application of a test, founded on the fact that nitrous acid readily liberates iodine from its combinations. Solutions of iodide of potassium and starch are, therefore, added together with some mineral acid, and if nitrites be present a deep blue coloration is at once produced. Mr. Young concluded by referring to another class of impurities occasionally found in water, viz, lead (which is, perhaps more dangerous than any of those before mentioned) and iron. These substances, generally derived from the pipes, etc., through which water is conveyed, are not found in such large quantities as might be expected, owing to the fact that the salts of calcium and magnesium, already alluded to, form insoluble double salts with them, lining the pipes and protecting them from the action of the water. If present, however, they could easily be detected by the black precipitates thrown down on passing sulphuretted hydrogen through the water. The lecture which occupied upwards of two hours in delivery treated the subject in a most masterly manner, and being illustrated by numerous experiments, every test and operation was strongly impressed on the minds of the audience.

A very hearty vote of thanks to Mr. Young for his services, brought the proceedings to a close.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 1st April 1875, Professor Abel, F.R.S., in the chair. After the usual business of the Society, a paper describing some "Researches on the Action of the Copper Zinc Couple on Organic Bodies: VIII. On Chloroform, Bromoform, and Iodoform," by Dr. J. H. Gladstone and Mr. A. Tribe, was read by the latter. Dr. W. A Tilden then read a paper "On the Action of Nitrosyl Chloride on Organic Bodies: II. On Turpentine Oil." The action gives rise to a molecular compound of terpene and the chloride, which by the action of alcoholic potash yields *nitrosoterpene*, $C_{10}H_{15}NO$. Dr. A. W. Hofmann made two communications to the Society, one, on the decomposition of the fulminates by ammonia and by sulphuretted hydrogen, the other, a striking lecture experiment to show the atomic relations of oxygen and chlorine. The meeting was then adjourned until Thursday, 14th April, when papers were to be read on :—"The Gases enclosed in Coal from the South Wales Basin and Gases evolved by Blowers and by Boring into the Coal itself," by F. W. Thomas; "On Narcotine, Cotarnine, and Hydro-Cotarnine," by G. H. Beckett and Dr. Wright; "Note on Isomeric Change in the Phenol Series," by Dr. Armstrong; "On Andrewsite and Chalkosiderite," by Professor Maskelyne; "An Examination of Methods for effecting the Quantitative Separation of Iron, Sesquioxide, Alumina, and Phosphoric Acid," by Walter Flight.

PARIS SOCIÉTÉ DE PHARMACIE.

A meeting of the above Society was held on Wednesday, March 3, under the presidency of M. Planchon, who, after the preliminary business had been transacted, read a paper on Jaborandi, giving a very detailed description of roots, branches, and stalks of different sizes, leaves of various ages, inflorescence bearing buds and flowers, and an imperfect fruit, which had been picked out from a parcel of jaborandi received at the Pharmacie Centrale.

M. Planchon is of opinion that there can be no doubt the plant belongs to the genus *Pilocarpus*, of which it presents all the characters, the disposition of the flowers and their structure being exactly those of plants of that genus. The fruit resembles in all points those in the museum belonging to the genus *Pilocarpus*, and particularly *P. heterophyllus*, A. Gray; the fruit of *P. pennatifolius*, Linn., is unknown. Referring to the question whether the occurrence of glabrous and very pubescent leaves indicates that they are derived from plants of two different species, he remarks that if they occurred alone it might have been supposed that they were, and the opinion would have received support from the positions occupied by the inflorescence, it being sometimes terminal and sometimes occurring upon branches which had already lost their leaves. But after examining some specimens bearing several branches upon the same stem, he thinks he is justified in saying that leaves exist in all the gradations between the glabrous and pubescent forms. Moreover, Lemaire's diagnosis of *Pilocarpus pennatifolius** indicates that the plant, though at first pubescent, becomes glabrous proportionally as it increases in age: "frutex prima juventate totus puberulus, deinde glabratus." The difference in the position of the inflorescence does not appear to be accompanied by a corresponding difference in the organs of vegetation and is not sufficient to divide the plants into two true species. Assuming, then, that the specimens examined were the products of a single species, M. Planchon considers that, notwithstanding they are yet imperfect, they confirm the original conjecture of Baillon that they are referable to *Pilocarpus pennatifolius*. The larger glabrous leaves correspond in all respects to those of that species in the herbarium of the museum. The flowers, however, differ in some respects, but the differences he considers are probably individual rather than specific. The terminal inflorescence hitherto discovered with the jaborandi is not sufficiently developed to compare with the adult inflorescence of the museum specimens, whilst the latter do not include a plant having lateral inflorescence. Examined under the microscope the roots were found to contain numerous large resiniferous cells in all the layers, except the thin exfoliating periderm. In the bark, below the suberose layer, is a circle of well characterized glands, analogous to the oleiferous glands of *Citrus*; whilst in the liber layer are sclerogenous cells, containing a drop of resinous matter, and more internally are resiniferous cells resembling those of the root. The anatomical structure of the leaf is rather simple. An amorphous cuticle covering a single layer of square or rectangular cells represents the epiderm. Upon the upper side, immediately below this epiderm is a series of long narrow cells, extending perpendicularly to the surface, crowded together and containing chlorophyll. Lastly there is a loose parenchyma of cells also containing green granular matter. This parenchyma, frequently interspersed with air lacunæ, extends to the epidermic layer of the lower surface. Here and there fibrovascular bundles occur, corresponding to the section of the nerves, and in the middle, at the point where the median nerve would be found, is a well developed bundle of ligneous tissue intermixed with spiral vessels. In the middle of the parenchyma are large translucid oleiferous glands, formed of intercellular cavities, surrounded on all sides by special cells, which are smaller than those of the surrounding tissue, and which form a continuous wall to the gland. These cells are scattered here and there through all the section; sometimes they approach the upper surface, breaking in upon the layers of chlorophyll cells, but the greater number occur towards the lower surface. The stomata of the leaves, which are especially numerous on the under surface, are rather small, ellipsoid in form and surrounded by two reniform cells; the hairs are simple and unicellular. The thick tawny-grey or brown petals of the flower are marked by numerous well-developed oil

* Lemaire, 'Jardin fleuriste,' vol. iii., pl. 263.

glands, and it was noticed that when moistened with warm water for the purpose of dissection they gave off an odour which was much finer and more agreeable than that of the leaves, and resembling the smell of citron. In reply to a question, M. Planchon stated that from recent experiments the stem bark appeared to possess the same properties as the leaves.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture V.

On the secondary action of Alcohol on the animal functions, and on the physical deteriorations of structure incident to its excessive use.

It is my business in this course of lectures to treat upon the specific action of absolute alcohol. I have therefore specially avoided all reference to the spirituous drinks of which it forms a part. As a rule, in every form of strong drink the source of the action of it, for good or for evil, is the spirit it contains, and the influence of the drink is potent according to the amount of that spirit present in it. To put the matter simply, if all the liquors sold under the name of wine, brandy, gin, rum, whisky, ale, stout, perry, cider, and so forth, were divested of their alcoholic spirit, they would contain comparatively little of anything that would affect those who partook of them.

Deleterious Additions to Alcoholic Drinks.

But as I am about to-night to speak of the deleterious action of alcohol, it is fair I should admit that some bad effects do spring from so-called wine and kindred drinks independently of the pure spirit they contain. Something less of evil than now obtains would be secured if none but natural wines and ales were drunk by the people. To return to the times before Brantwein was distilled, and to have no intoxicating beverages save pure wine and sound ale, were doubtless an improvement on the state of things which now exists; for in truth at the present time the characters of pure ethylic wine are hardly known. A *bonâ fide* wine derived from the fermentation of the grape purely cannot contain more than seventeen per cent. of alcohol, yet our staple wines, by an artificial process of fortifying and brandying, which means the adding of spirit, are brought up in sherries to twenty and in ports to even twenty-five per cent. Some wines and spirits are believed to be charged with amylic alcohol. Other wines are charged with foreign volatile substances to impart what is called bouquet, and still other so-called wines—I allude specially to the effervescing liquids sold under that name—are actually often undergoing the fermenting process at the time they are drunk, and thus are invited to complete their fermentation in that sensitive bottle, the human stomach.

If the subject were specially looked into, a very important chapter of facts might be collected bearing upon the injurious effects of these additions to ales, wines, and spirits. I have noticed the evils that follow upon the administration of an alcoholic drink that has been adulterated with amylic alcohol, and have shown that they are exceedingly serious. The disturbances excited by the other faults, when they do not arise from excess of absolute alcohol, are shown in symptoms of indigestion and in the promotion of an acid condition of the secretions of the body beyond what is natural.

Presuming, therefore, it be actually determined by any one that he will take some alcoholic fluid, he will do nearest to that which is most wise if he take wines or other spirituous drinks in which the quantity of alcohol is simply confined to the natural amount, in which the process of fermentation has ceased, and in which no foreign substance has been introduced to add either bouquet, body, piquancy, narcotizing influence, or other artificial quality.

Absinthe.

The admitted addition of some actively poisonous substances to alcohol, in order to produce a new luxury, is the evil most disastrous. The drink sold under the name of *absinthe* is peculiarly formidable. In this liquor five drachms of the essence of absinthum, or wormwood, are added to one hundred quarts of alcohol. Thus the liquor is not only very strong as a mere alcoholic drink, but it is charged with another agent which has been discovered to exert the most powerful and dangerous action upon the nervous functions. The essence of absinthum in doses of from thirty to fifty grains produces, in dogs and rabbits, signs of extreme terror and trembling, followed by stupor and insensibility. In larger doses it causes epileptiform convulsions, foaming at the mouth, and stertor of the breathing. Its effects, as they occur from the taking of it in the form of absinthe in man, have been most ably described to me by one who indulged in it until it induced in him the peculiar epileptiform seizure. He described the effects as resembling those produced by *haschish*, the narcotic of the East which has been known for so many ages as the *nepenthes* of Homer, and which owes its properties to extract of Indian hemp or *Cannabis Indica*. The partial insensibility caused by the absinthe is attended with the ideal existence of long intervals of time, in which the events of a whole life are arrayed and appreciated, to be succeeded by terrific hallucinations and intellectual weakness, ending in unconscious struggling as if for life. In time, if the use of the absinthe be continued, these phenomena become permanently established and the result is inevitably fatal.

The doubly poisonous absinthe is made the more seductive to its victims by the fact that it excites a morbid craving for food which is never felt except when it is tempted by the destroying agent. Indeed, such are the terrible consequences incident to this agent, that I agree with Dr. Decaisne in maintaining that it ought, by legal provision, to be forbidden as an article for human consumption in all civilized communities. Even in small quantities taken daily, say one or two wine-glassfuls, it causes quickly a permanent dyspepsia, and what is of still more consequence it tempts its victims on and on, so that they cannot take food until absinthe has prompted the desire for it, by which time they are too often hopelessly and mortally in its power.

Until recently absinthe has not been publicly offered for sale in this contry on a large scale. But now unhappily the poison is openly announced even here, and the consumption is on the increase; I am doing therefore a public duty in denouncing its use solemnly from this platform, whence so much that is beneficial to society has for a century past been spoken.

Addition of other Agents.

The intentional additions of poisonous agents to the alcohol of ales, wines, and spirits, pale when absinthe appears in sight, but they are not to be ignored. It is true that we very often hear accounts of the effects for evil of bad wine, when, in fact, the evil is due to the excess of ordinary alcohol that has been taken by the complainant. At the same time it is not to be denied that there exists in our midst a system of mixing, compounding, blending, and reducing wines and spirits, which, carried even to artistic perfection, is additionally prejudicial to the business of selling the various alcoholic beverages.

To be just to our own age, this artistic performance is not an invention of it. The adulteration of wine is indeed one of the oldest devices, extending from the Greeks and Romans onwards to this day. In the Middle Ages many prohibitory acts were passed against it by various governments. As late as the close of the seventeenth century an Act was passed by Duke Everhard Louis of

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts.*

Wurtemberg making it an offence punishable with death and confiscation of property to adulterate wine with bismuth, sulphur, or the salt of lead called litharge, now known as the yellow protoxide of lead. In the year 1705-6, John Jacob Ernhi of Eslingen was actually beheaded for carrying out adulteration with the forbidden poisonous lead compound.

Into our modern civilization a different system of treating strong drinks, in order to rectify bad qualities or to impart new, is as a rule followed. The plan of using gypsum or sulphate of lime to remove the acidity of wine, a practice that was followed both by the Greeks and Romans, is however still resorted to; so also is the practice of using lime for the same purpose, and for which Jack Falstaff so severely criticizes the landlord of the "Boar's Head":—

"You rogue, here's lime in this sack too. There is nothing but roguery to be found in villanous man: yet a coward is worse than a cup of sack with lime in it; a villanous coward."

But on the whole, the new day has brought new plans and new inventions, having reference to the different forms of drinks, namely, ales, wines, and spirits, which pass from the hands of the vendor to the consumer.

(*To be continued.*)

Parliamentary and Law Proceedings.

The Sale of Vermin Killers.—A Chemist and Druggist Fined.

At the Wolverhampton Borough Court, on Monday, April 11, Messrs. W. J. Reade and Thomas Reade, chemists and druggists, of Victoria Street, were summoned for having on the 3rd of April unlawfully sold to Samuel Harvey a packet of Battle's vermin killer containing strychnine, Harvey not being then known to them, nor having been introduced to them by some person known to them, contrary to the Pharmacy Act. The proceedings arose out of an assistant to the defendants named Sibthorpe selling a packet of "Battle's Vermin Killer" to Samuel Harvey, who with it attempted to commit suicide.

Mr. Thomas Reade, who represented his firm, said they pleaded not guilty to the charge. They admitted that they sold the vermin killer, and that it contained strychnine, but their assistant knew the man Harvey to whom he sold it, and therefore they contended that they had complied with the Act.

Samuel Harvey was then called and said that he did not remember going to Messrs. Reade's shop on Saturday week. He was so drunk that he did not know where he went, nor he did not remember anything about it. In reply to Mr. Reade, witness said he did not know whether he was drunk when he went into their shop. If he did go into the shop he must have been drunk. He had been drinking all the previous week, and he attributed his loss of memory to being drunk.

Stephen Sibthorpe, assistant to the defendants, said Harvey came into Messrs. Reade's shop between six and seven o'clock on Saturday night week. He asked witness for two packets of rat poison, and said he supposed he would have to sign for it. He asked for two threepenny packets, and witness supplied him with one sixpenny packet. After entering the sale of the packet in their "poison book," Harvey signed the book, but did not give his address.—In reply to the Bench, witness said he knew Harvey by sight, as he had frequently come to the shop for oil for Mr. Hunter, the manager at Messrs Chubb's works, Horsley Fields. When witness sold the poison he took Harvey to be sober.

Mr. Reade here handed up a book provided by them for the sales of poison to be entered in. He said it did not provide for any address, but only for the signature of the purchaser.—In reply to the Bench, Mr. Reade said he did not produce the book in which the sale of the poison to Harvey was entered. The book was being used at their place of business. They were quite in the hands of their assistant Sibthorpe. They had complied with the Act by the fact of Harvey having signed their book. The Act did not say that they must be on visiting terms with the purchaser, or that they must even know his address.

Mr. Barber (deputy magistrates' clerk) said the object of the Act was to know the purchaser's whereabouts in the event of his being wanted.

Mr. Umbers (magistrates' clerk) observed that the Pharmacy Act stated that it was unlawful to sell poison to any person unknown to the seller, besides which the seller should, before delivery of a poison, make an entry in a book kept for the purpose of the name and address of the purchaser, and the quantity and kind of article sold.

Mr. Barber remarked that if Harvey's attempt to commit suicide had proved fatal they (the defendants) would not have known where to find him.

Mr. Reade said the object of the Act was not to prevent suicide but to prevent murder.

Sir John Morris said the assistant had failed to comply with the regulations of the Act by not entering Harvey's address in their book.

Mr. Reade stated that was an omission, but their book was issued by a very respectable firm, and it did not make any provision for the address of the purchaser to be entered.

Mr. Sibthorpe said he knew the address of Harvey from the fact of his having been employed at Messrs. Chubb's.

Sir John Morris: But you did not conform with the Act by putting his address in your book.

Mr. Umbers: Are you prepared to be more careful in future?

Mr. Reade: Yes, sir, but we have always been scrupulously careful about the sale of poisons.

Mr. Sibthorpe: I have frequently refused to sell poisons to persons whom I did not know.

Sir John Morris: The Bench have no other course to pursue than to decide for a conviction to take place. The man (Harvey) was evidently drunk, and in an unfit state to be supplied with poison, and you have not complied with the Act.

Mr. Reade: I think that man's evidence is not fit to be put against ours, who have a good character and reputation to maintain. I think you ought not to allow that man's evidence to go alongside ours.

Mr. Barber: The question is not whether the man was sober or drunk, but whether you have complied with the regulations of the Act.

Sir John Morris (to Mr. Reade): It is clear you have not complied with the Act, and we are bound to convict. You will be fined £1 and costs.

Mr. Reade: We tried to conform to the Act, or we should not have made any register of the sale at all.

Sir John Morris: There is a trifling omission which might have resulted in very serious consequences.

A fine of £1 and costs, amounting altogether to £3 1s., was then imposed, and Mr. Reade at once paid the money. —*Midland Counties Express.*

Examination Papers.

At Bow Street Police Court, on Saturday, April 10, Samuel Cowap, aged 21, described as a chemist's assistant, residing at 42, Castle Street East, Oxford Street, was charged on remand before Mr. Flowers, with inciting one George Austin to steal an examination paper of the Pharmaceutical Society from his employers, Messrs. Stevens and Richardson, printers, of 5, Great Queen Street, Lincoln's Inn Fields.

Mr. Douglas Straight, instructed by Messrs. Flux and Co., solicitors to the Pharmaceutical Society, again prosecuted.

James Wallis Butcher, detective sergeant, said that upon Saturday, April 3, he went, according to instructions, to the corner of Tottenham Court Road, about 4 o'clock in the afternoon. He saw Austin there and saw him meet with the prisoner and go with him into the Horse Shoe Tavern, at the corner of Tottenham Court Road. Austin handed the prisoner a paper, and he in return handed something back to Austin, who threw it on the counter as if to test it, and witness then saw it was half a sovereign. Witness immediately said to the prisoner: "I am a detective officer, and shall take you into custody on the charge of inciting this man (Austin) to steal the examination paper of the Pharmaceutical Society from his employers." The prisoner replied: "My God! I have not looked at the paper. You are too fast this time. Will you let me go?" Witness said he would have to go to Bow Street, and on the way to the station prisoner said: "I don't know what I shall do. I did not think of this. I am in a respectable position as a chemist's assistant. I was to go up to an examination on Monday, and have paid the fee, and studied hard, but I did not think I should pass and so took these means for getting the paper to enable me to do so." Witness asked him where he was employed, and he said at Mr. Bird's, Castle Street East. Witness went there and found his statement correct. At the station prisoner was searched and the examination paper in question found on him. Witness had ascertained that the prisoner had previously borne a very good character, and Mr. Bird, his employer, was in court to speak for him and was also willing to continue him in his employ.

This being the case for the prosecution,

Mr. Straight said that since the last occasion of appearing at this court, on Monday, April 5, he and those for whom he appeared had had the opportunity of considering this case. Upon the last occasion he (Mr. Straight) had intimated that under certain circumstances, namely, if the prisoner had been employed by some professional "coach," who wished to obtain the paper to enable him the better to "cram" his pupils, the case would assume a very serious aspect. That was the case in 1871, when the Apothecaries' Company prosecuted and the then prisoner was sentenced to twelve months. But in this case full investigation had been made and the result was that the prisoner was shown to be a young man in the confidence of his employer and bearing a very good character, but who had, unfortunately, without thinking of the consequences, given way to the temptation of making more sure of passing his examination by obtaining this paper. Under these circumstances the Society had left the matter entirely in his (Mr. Straight's) hands, and what had decided him in taking the course he was about to adopt was that Mr. Bird, the prisoner's employer, was present to speak for him, and also was anxious to continue to employ him, and further that he had received a letter from Mr. Cooper, the rector of the parish in which the prisoner lives, in which he says he has known the young man for a long while and was surprised, judging from his previous upright behaviour, to hear that he had thus given way to temptation. Having thus received from all sides testimony to the prisoner's previous good character, the Society did not wish to press the matter against him. At the same time they wished the public to perfectly understand that they were guided solely by the peculiar facts of this case. Any repetition of the offence will not be passed over in this way. Mr. Straight concluded by asking his worship's permission, under the peculiar circumstances of the case, and as the offence was a misdemeanor, to withdraw from the prosecution.

Mr. Flowers said that he felt no difficulty himself in adopting this course. He had thought all along that this was a very different case to the one in 1871. He was glad to see the prisoner's employer, Mr. Bird, become bail for him on the last occasion as it proved that Mr. Bird had a good opinion of him. It was also evident from the prisoner's behaviour in the dock, that he was very sorry for what he had done. Had he had the pluck to go up for the examination honestly, he (Mr. Flowers) believed the prisoner would have passed. Had this been a case of a man who had obtained the paper to enable him to "coach" pupils and so defraud the Society, the punishment would have been severe, for there was no calculating the amount of harm that might be done by young men being placed in positions they were not qualified to fill, owing to their having passed examinations dishonestly. After fully considering, however, all the facts of this case and all that Mr. Straight had urged in the matter, he (Mr. Flowers) should offer no objection to the course the Society proposed to take, and the prisoner might therefore be discharged. Mr. Flowers also expressed a hope that this case might prove useful as a warning to others.

The Residue from the Manufacture of Aërated Waters.

At Marlborough Street Police Court, on Thursday, April 8, Mr. Thomas Codey, mineral water manufacturer, No. 88, Whitfield Street, St. Pancras, was summoned before Mr. Knox for allowing the discharge of mineral waters and other offensive matters and the deposit of the residue from the manufacture of aërated waters into the sewers, thereby causing a nuisance.

Mr. Cooper, solicitor to the Vestry of St. Pancras, prosecuted; and Mr. Edward Lewis was retained for the defence.

Mr. Cooper, in opening the case, said that one flushman had been killed on entering the sewer, and others had been so affected that they refused to go down. The defendant, having had notice given to him, discontinued for some time the practice of discharging refuse into the sewer, thereby evolving a gas of a most injurious nature, but on the 18th February, it having been found that he had resumed the practice, the present proceedings were instituted.

John Hartley, inspector of nuisances for St. Pancras, proved serving notice on the defendant to discontinue the nuisance. He went down the sewer on the 18th February, and saw some refuse from the drain brought out by a man named Francis, and saw it taken away. The refuse was very offensive matter; it made him giddy when he stood over it. The matter appeared to be a sediment of lime.

Thomas Francis, foreman of the flushers of St. Pancras, proved taking some of the matter from the sewers, which he considered was dangerous to health. One flusher had lost his life through it; others had been made ill, and he became ill in consequence of inhaling the stuff, some of which he took to the analyst at Guy's Hospital.

Replying to Mr. Lewis, witness said he had been ill previously. After going down the sewer he was attacked with giddiness. He took some medicine the next day.

Medical evidence having been given,

Dr. Stevenson, lecturer on chemistry at Guy's Hospital, stated that he had examined the stuff taken from the sewer. The deposit was a white solid substance, such as forms the refuse from aërated water factories and ordinary sewage. The refuse from soda water consists of whiting and a product of the action of oil of vitrol and whiting, known as sulphate of lime. The refuse was odourless, but when it is shut up with sewage it undergoes decomposition and loses oxygen. The carbonic acid of the sewage then by its action on the decomposed refuse liberated a poisonous gas from it, known as sulphuretted hydrogen. The white refuse also detained the sewage mechanically; that caused its decomposition *in situ*. The refuse thus acted deleteriously both by its mechanical and its chemical actions.

Mr. E. Lewis was prepared to show by other professional evidence that the charge of nuisance could not be sustained, and that no danger to health was to be feared from the practice of the defendant.

Mr. Wanklyn, analyst, had examined the soda water refuse, and found that it contained two per cent. of free sulphuric acid. Such a refuse if diluted with water would act as a disinfectant, and would not liberate noxious gases from sewage, for the quantity of liquid would be more than sufficient to dissolve all the sulphuretted hydrogen liberated by the action of the acid.

An application having been made for an adjournment, in order that further rebutting evidence might be produced,

Mr. Cooper would not oppose the application, but he hoped an early day would be fixed for a decision, because it was a matter affecting not the health only of flushmen, but of the inhabitants of the district.

Upon the case being resumed,

Mr. Cooper wished to put in the joint opinion of the Solicitor-General and Mr. H. B. Bland.

The opinion was to the effect that a magistrate could make an order on the manufacturers, under section 12 of the 18th and 19th Vict., cap. 121. After reciting several decisions and cases, the counsel went on to say that the case submitted to them was an important one to the Vestry of St. Pancras, as the men sent into the sewer to flush it as required could not do their work without having their health injured. As the question was not free from doubt—though if a magistrate gave an order of prohibition they had no doubt it would be sustained—they would suggest that the magistrate if requested should state a case for the opinion of the superior courts.

Mr. Knox said he was prepared to give his decision, and, after referring to cases decided by Justices Blackburn and Mellor, remarked that there was a conflict of evidence in the case before him—one scientific gentleman stating one thing and another something different. Under these circumstances he felt compelled to rely on the evidence of the medical gentleman on the part of the parish, that putting the refuse matter into the sewer was injurious to the public health, and he should therefore make an order that the nuisance be discontinued, and if Mr. Lewis thought proper to ask for a case he would give one. At the same time he would suggest to the defendant the expediency of mixing water freely with the refuse so as to render it harmless in its character.

Prosecution under the Adulteration Act. Alleged Adulteration of Vinegar.

At the Stone Petty Sessions the adjourned hearing of a summons against Mr. Thomas Slater, grocer and druggist, of Stone, for selling vinegar alleged to be adulterated was proceeded with on Tuesday, March 30. The proceedings were taken by Mr. Knight, inspector under the Adulteration Act, whose assistant procured a pint of vinegar at the defendant's shop, on January 21, which was afterwards submitted to Mr. Scott, the county analyst, and certified by him to be adulterated with some preparation of or containing lead so as to be injurious to health and also with sulphuric acid. The defendant was not satisfied with the result of the analysis, and at his request the case was adjourned in order that an independent analysis might be obtained. Messrs. Hill and Evans, the manufacturers of the vinegar, having in the meantime become interested in the case with a view to establish the purity of the article manufactured by them, not only was the remaining portion of the vinegar purchased for Mr. Knight sent to be tested by Dr. Thudichum, but two other samples of the same vinegar were sent respectively to Dr. Letheby and Dr. Voelcker. On the present occasion, Mr. C. Fulford, barrister, appeared for the prosecution, and Mr. J. Underhill, barrister (instructed by Mr. Southall, of Worcester), in behalf of the manufacturers. Drs. Letheby and Voelcker were in attendance to state the result of their analyses, but Dr. Thudichum was not present, and Mr. Underhill objected to his certificate being taken as evidence. Mr. Fulford said that Dr. Thudichum would have been in attendance only that the prosecution wanted to save expense to the defendants. Dr. Thudichum would require a twenty-five guinea fee to come down, and they did not know that there were gentlemen connected with this case who were prepared to pay all these costs, or Dr. Thudichum would certainly have been there. It was a usual thing in these cases to save expense by accepting the certificate as evidence. If in this case the certificate were not admitted, an adjournment must take place. Mr. Underhill said the question was such an important one that he should have thought not only Dr. Thudichum but Mr. Scott would have been present. He would suggest a course, however, which might obviate the necessity for Dr. Thudichum having to attend, and it was that they should proceed with the case as far as they could, and examine witnesses *pro* and *con.*, and if at the close the Bench were not in a position to pronounce a decision, then that an adjournment should take place for the attendance of Dr. Thudichum. This course having been agreed to, Mr. Fulford proceeded to recall the circumstances of the case, and to refer to the certificate given by Dr. Thudichum, which, it appeared, stated that the vinegar was adulterated with sulphuric acid so as to be injurious to health, but made no mention of lead. The learned counsel pointed out that there would be a difficulty in showing that the second samples were taken from the same barrels as the first sample, and argued that the most reliable test must be that made upon the remaining portion of the article purchased for the inspector. John Johnson, the person who bought the vinegar for Mr. Knight, having been cross-examined at considerable length, Mr. Underhill then addressed the Court for the defence. He said they desired in this case to fight the broad question whether that vinegar was adulterated or not, and having mentioned several instances in which Messrs. Hill and Evans had victoriously established the purity of their vinegar, he proceeded to comment upon the fact that Mr. Scott had found lead in the vinegar, but that Dr. Thudichum had found only sulphuric acid or oil of vitriol. The difference between the two certificates showed either that one analysis was very imperfect, or that there must be some considerable mistake on the part of one or both of the analysts. When doctors disagreed, who was to decide? He concluded by sketching out the evidence as testified to by the following witnesses:—James Burnett, assistant to the defendant, deposed that he supplied Mr. Knight's assistant with a pint of vinegar on January 21. Some time afterwards he drew off a pint of vinegar from the same barrel, and it was put into a bottle and sealed by Mr. Slater in witness's presence. That bottle was sent to Dr. Letheby by railway. Subsequently he drew off a further quantity, which was also put in a bottle and sealed, but he did not know of his own knowledge to whom it was sent. The vinegar was just in the same state as when it came from Messrs. Hill and Evans. Cross-examined: They kept two kinds of vinegar at the shop; one kind at 2*d.* and the other at 3*d.* a pint. Johnson bought the cheapest kind. Dr. Letheby, Professor of Chemistry at the College of the London Hospital, said that on March 1 he received a bottle of vinegar for analysis from Mr. Slater. He made a very careful and complete analysis of it. He could say with the utmost confidence that there was not a trace of free sulphuric acid in the vinegar. He found traces of combined sulphuric acid, but that was contained in the water from which the vinegar was made, and was not at all injurious to health. Dr. Letheby also showed that unless a peculiar test were made the combined sulphuric acid, which was perfectly harmless, might be mistaken for the noxious element of free sulphuric acid. The analyst might have jumped to a conclusion, as a similar error had been committed by chemists of great reputation. Of lead he found no trace whatever. Dr. Voelcker, who had made an entirely independent analysis of the second bottle, corroborated Dr. Letheby's evidence in almost every particular. Mr. Fulford thought, after the evidence that had been given, it would only be fair that Dr. Thudichum and Mr. Scott should be present, and have an opportunity of upholding the conclusion to which they had come. It must be borne in mind that there was no means of ascertaining whether Barrett was perfectly accurate in his recollection of what he did—whether, in fact, the vinegar was the same as that sold to Johnson. The Bench adjourned the case for a month.

Suicide by Laudanum.

An inquest was held at Liverpool, on Saturday, the 3rd inst., respecting the death of Mr. S. Perris, late librarian at the Lyceum Library, Bold Street. It appeared that the deceased had, in consequence of bad health, been unable to attend to his duties; the sub-committee had therefore passed a resolution that he should be presented with a gratuity of £100, and that his future services should be dispensed with. He became very depressed in consequence of the loss of his situation, and on the Thursday morning previous to the inquest he was found lying dead in the library opposite his father's picture, and a broken bottle that had contained laudanum was in the fireplace. Dr. Dawson said he had no doubt the death of deceased had been accelerated by laudanum.

The jury returned a verdict that death had been caused by poison taken whilst deceased was labouring under mental derangement.

Notes and Queries.

[435]. CEMENT FOR COMPOSITION MORTARS.—Can any reader tell me of a satisfactory cement for mending large broken composition mortars? I have tried several, but they are all unsatisfactory.—"VINEGAR."

[436]. UNG. PAGENSTACHEN.—Can anyone give me information about Ung. Pagenstachen? I had a prescription presented the other day with ʒij of said Ung. and ʒi Adipis, and am utterly at a loss to know what it is.—W. B. C.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Glasgow Memorial.—Explanatory Note.

Sir,—Will you kindly permit us to explain in connection with this memorial that by an unfortunate oversight, Mr. Frazer had not been supplied with a copy of it while asking him to support its prayer; hence, we presume, he was unable at the moment to decide in what form he should bring it before the Council. It is only right also for us to state that the only meeting in connection with it at which Mr. Frazer was present was the meeting of the Glasgow Council where there were nine members (including Mr. F.) present; but that the draft memorial had previously been adopted by a meeting of the trade, convened by circular, at which there were about sixty representatives, both town and country members, while many who could not get to the meeting sent letters of apology expressing their entire sympathy with the objects of the meeting, which were, of course, set forth in the circular calling it. We think it only due to ourselves also to point out an awkward error which has crept into the second suggestion, namely, the words "That the Board of Examiners be ballotted for from year to year as in the election of Members of Council, that is to say," should read thus: "That the Scotch Board of Examiners be ballotted for from year to year by the Council as in the case of the London Board last year, and that."

We gladly further take this opportunity afforded us of disclaiming altogether the impression which seems to have been made on the minds of Messrs. Betty and Mackay, regarding the memorial, namely, that it was intended in any way to impugn the honour of the Board of Examiners in Scotland. Nothing could have been further than this from the intention of the memorialists, nor do we see how anyone in carefully reading the memorial can form such an estimate of it; we know at all events that it was not the desire of the meeting to cast the slightest reflection upon either past or present members of the Examining Board in Scotland. Not only so, but, although Mr. Mackay has evidently forgotten it, circulars convening the two or three public meetings, which were held to discuss the question and at which the draft memorial was adopted, were sent to several members of the Examining Board at Edinburgh, Mr. Mackay, if we mistake not, being amongst the number, while the meetings and their objects were notified in reports published in the *Pharmaceutical Journal* and *Chemist and Druggist*.

In conclusion, we cannot but express regret that seeing Mr. Frazer declined to discuss the substance of the memorial until he found himself in order to do so in a formal manner, that the matter on its merits was entered upon at all by any of the other members of Council present, or that you yourself, sir, should have taken it up in your editorial columns. We earnestly hope that the memorial will receive that fair and impartial consideration that its importance demands when it comes before the Council through Mr. Frazer's motion next month.

JOHN CURRIE, *President.*
JAS. M. FAIRLIE, *Secretary.*
Glasgow Chemists and Druggists' Association.

The Glasgow Memorial.

Sir,—The extraordinary production purporting to emanate from the Glasgow chemists and druggists (and signed by Messrs. Currie and Fairlie), read at the Council meeting of 7th April, has all the appearance at the present moment of being a huge joke, played on the Council at the expense of our friends of the West of Scotland. This opinion is confirmed not only by the nature of the meeting at which the extraordinary resolutions were adopted, a meeting apparently partaking very much of the character of the historical meeting of the Tooley Street tailors, but it is confirmed more especially if we notice that it was quite evidently intended that the document should reach the Secretary's hands on the 1st of April, All Fools' Day. Under these circumstances it is quite possible that the production may have too much importance attached to it; and yet seeing the Council have given some little consideration to it, and seeing also that our respected Scotch member, Mr. Frazer, has fallen innocently into the trap, I venture, at the risk of having it voted an infliction, on stating one or two plain truths by way of reply to the memorial.

In doing so I pass in silence the fling which Messrs. Currie and Fairlie, together with the five other unnamed gentlemen present at this meeting, have at all and sundry connected with the examiners and examinations; nor do I in the meantime intend calling particular attention to the wonderful logic running through the whole production, intending to prove that examinations, and more especially examinations in Edinburgh, and scarcity of apprentices and assistants are cause and effect. In these respects I will let the memorial speak for itself, and I have a strong conviction that comment is superfluous.

There is one point, however, which requires serious inquiry and explanation, viz.:—Why, and under what conditions, Mr. Fairlie signed this memorial? As Secretary of the Glasgow Chemists and Druggists' Association it is highly probable that Mr. Fairlie had a considerable hand in drawing out and framing this memorial; but whether he drew it out or not he must at least have been conversant with its contents previous to signing it. Now, did Mr. Fairlie, or did he not, give the Glasgow Chemists' Association, or the Council of the Association, or the six gentlemen present along with himself at this extraordinary meeting, any information on the following points, *videlicet*, Did he inform them of an Executive or Council in Edinburgh whose duty it was to nominate, not elect, examiners for Scotland? Did he tell them that this Executive or Council was popularly elected after the manner of the London Council, by sending ballot papers throughout the length and breadth of Scotland, and that gentlemen were nominated annually from almost every town of any importance in Scotland? And further, Did he tell them that he himself had sat on this Executive for at least the last two years, and never once during that time suggested any improvement on this mode of nominating the examiners (as indeed he could not), nor once complained of the "limited area" from which the examiners were drawn, or of the influences "detrimental to the interests" of the candidate for examination under existing arrangements? If he did not explain to them all the foregoing, previous to agreeing upon and drawing out this memorial, then, I for one, would not care to characterize his conduct; if, on the contrary, he did, he confessed himself guilty of the grossest dereliction of duty, not only to the constituency which he represents, but also to his brethren of the executive, and in either case his signing this document is almost incomprehensible. It is all the more incomprehensible if we bear in mind that Mr. Fairlie knew, or would have known had he attended the meetings, that year by year efforts had been made to draw examiners from districts other than Edinburgh, not even excluding Glasgow, and that year by year they had failed, much to the disappointment not only of the executive but of the old examiners—failed from the simple fact that no one cared to enter on duties so irksome, so unthankful, and above all, so unprofitable. If Messrs. Currie and Fairlie's memorial draws the attention of the Council in London to this fact, it will probably induce them to consider the hardships of the examiners as much as the examined, and the executive as well as the Board of Examiners in Scotland may thus ultimately have cause to be even grateful for the scant courtesy (to call it by no harder name) which prompted and produced this memorial to the London Council without note or whisper to their Edinburgh brethren.

I feel I have already exceeded the limits allowable for a letter, but if you will kindly grant me space on another occasion, I will return to the subject of this memorial with more immediate reference to the points raised in it, of examiners, examinations, and scarcity of assistants.

SCOTUS.

Sir,—Observing in the Journal of Saturday the 10th a memorial from the Glasgow Chemists and Druggists' Association, which contains many misstatements and altogether shows a great amount of ignorance, I feel inclined to dispute their arguments.

In the first suggestion contained in that memorial it is stated that it is the rule for other examining boards in Scotland to admit candidates for their respective examinations to a subsequent examination after having failed, and without extra fee. Were the memorialists meaning Good Templars? I am unacquainted with the manner they conduct their examinations, but I can assure your readers it is not the rule of any other examining body in Scotland. The only examination that a candidate has two opportunities of passing for one fee is the preliminary examination of the Faculty of Physicians and Surgeons of Glasgow, but that body retains £2 for candidates who fail in their other professional examinations. The last clause of the suggestion is so absurd and untenable that it would not be held by any examining body in Scotland.

As regards suggestion 2, it appears that the memorialists are thoroughly unacquainted with the manner in which examiners are appointed; and thus the memorialists may be misunderstood; for some time since a furious attack was made on the Edinburgh Council about the manner their business was conducted, and the manner in which the members were elected, which resulted in the election of one of our western brethren. Has he done anything by his appearance or non-appearance to remedy these defects; or did they only exist in imagination? Perhaps if a similar course were pursued with the present memorialists they would be thoroughly satisfied, and we should hear no more of Scotland's hardships in the west; but owing to the qualifications necessary to become an examiner this is impossible. That the examinations are not the cause of driving young men from the trade in Glasgow is clearly proven by the fact that so many are studying for the medical profession, where examinations are more stringent, and the time and money required much greater. The real cause lies in the fact that the hours are much longer and the salaries much smaller than in any other branch of industry in this populous centre; a great deal also depends on the readiness with which young men can obtain access into other trades and professions, medical education being more accessible here than in any other city. The allurements of position and a decent livelihood on the one hand far outbalance £60 per annum with night bell and no society on the other. That such are the opinions of a vast amount of the assistants in Glasgow may be presumed from the fact that at the Glasgow Chemists and Druggists' Association a motion has been before the meeting for the last two nights, to the effect that none but those who close their places of business at 8 P.M. shall be eligible for election as office-bearers; thereby showing an inclination to dispose of your memorialists, as their qualifications, if the resolution were carried, would be found enormously wanting. A great deal is made of the expense incurred by candidates travelling from Glasgow to Edinburgh and back; but what about candidates from Aberdeen and the north of Scotland? As the whole expense for a return ticket to Edinburgh is 4*s.* 6*d.*, they talk about nominal fees of 5*s.* for botanical and other classes here, yet make such a cry about this 4*s.* 6*d.* In conclusion I would recommend the Society to present the Glasgow Chemists and Druggists' Association with one of their Calendars, and I am confident any of the Licensing Boards and Universities in Scotland will, on application, kindly grant them a syllabus of the manner they conduct their examinations, in order that next time they memorialize they may have a correct idea of what they are memorializing about.

ASSISTANT.

Glasgow, April 13, 1875.

Messrs. Kimnond and Co.—We have seen nothing of the samples mentioned in your letter of the 29th ult.

A Founder.—Possibly from your point of view a different day would be preferable, but a change would probably cause quite as much inconvenience to other parties concerned.

W. W. W.—De Fivas' 'Grammaire des Grammaires' and Otto's German 'Conversation Grammar.'

R. H. R.—Rimmel's 'Book of Perfumes,' or Piesse's 'Art of Perfumery.'

J. T. Jenkins.—The books you already have are good, and sufficient for your purpose. We cannot recommend you to spend your money upon guides to examinations.

F. R.—*Daphne Laureola* is an evergreen plant with green flowers; the leaves are two or three times as long as those of *D. Mezereum*, and more leathery. The flowers of *D. Mezereum* are reddish purple, and appear before the leaves.

X. Y. Z. (Reading) and *X. Y. Z.* (Greenwich).—Section 16 of the Pharmacy Act, 1868, provides that nothing contained in the sections relating to Registration shall extend to or interfere with the making or dealing in patent medicines, or with the business of wholesale dealers in supplying poisons in the ordinary course of wholesale dealing.

J. T. C. Williamson.—(1) Bentham's arrangement would be accepted. (2) No notice need be sent previous to sending the collection.

W. R. F.—There is no section which relates to homœopathic medicines in the Act.

J. S.—Sect. 1 of the 'Act to Amend the Pharmacy Act, 1868,' provides that nothing contained in the registration clauses shall "prevent any person who is a member of the Royal College of Veterinary Surgeons of Great Britain, or holds a certificate in veterinary surgery from the Highland and Agricultural Society of Scotland, from dispensing medicines for animals under his care;" but this does not entitle him to keep open shop as a chemist and druggist.

W. Gunn.—(1) The plants could in all probability be obtained through one of the herbalists in Covent Garden Market. (2) *Anthoxanthum odoratum* is, we believe, the only indigenous grass known to yield coumarin.

"*Minor.*"—The phosphate of lime should be freshly precipitated and moist if possible. See a paper by Mr. Daniels, on p. 213 of the present volume.

J. S. is referred to the rule respecting anonymous communications.

COMMUNICATIONS, LETTERS, ETC., have been received from Mr. E. Davies, Mr. Cotterell, Mr. Hemsley, Mr. W. J. Barnes, Mr. Pocklington, A.C.

EXAMINATION OF SOME SPECIMENS OF OPIUM.

COMMUNICATED BY PROFESSOR FLÜCKIGER.

In the 'Pharmacographia,' published in common with my late friend Daniel Hanbury, we alluded (p. 58) to the analyses of several samples of opium. It is perhaps not quite useless to supply a few particulars referring to their examination. The following samples have been submitted to analysis in my laboratory, mostly by Dr. Buri:—

I. *Patna* garden opium, 1838, wrapped in wax. Under the microscope it is seen to consist for a large part of nice crystals, and to be devoid of starch. The crystals may partly consist of alkaloids, partly of sugar.

II. *Medical Indian* opium, 1852–1853, portion of a square brick. It contains large crystals, no starch.

III. *Abkari* provision opium, Patna, No. 5380 (see also 'Pharmacographia,' 49). Small crystals, no starch.

IV. Garden *Behar* opium; exquisitely crystalline, no starch.

V. *Malwa* opium, portion of a flat cake. This is not distinctly crystallized, and exhibits numerous starch grains, fraudulently admixed, starch not being a constituent of poppy juice.

VI. *Sind* opium, No. 28; large crystals.

VII. *Hyderabad*, Sind.

VIII. Opium from *Candeish*, not distinctly crystallized, containing some starch.

IX. *Persian* opium, presented to me by Mr. Howard (1872), highly crystalline, no starch.

X. *Egyptian* government opium, from Thebes, as exhibited in 1867, Paris Exhibition. Not distinctly crystallized.

XI. Opium produced in 1823 at Playford, Suffolk; containing large crystals.

XII. *English* opium, 1859, from Mr. Morson. Small crystals.

The process for the estimation of narcotine and morphine was that described in the 'Pharmacographia,' p. 59. The extract *a* of the following table is that afforded by means of boiling ether, with which the powdered opium had almost absolutely been exhausted by repeating the treatment with ether from about twenty to thirty times. The extract remaining after the evaporation of the ether was boiled with acetic acid, 1·04 sp. gr. This liquid, after the acid had been driven off, yielded *b, crude narcotine*, as a crystalline brownish mass. It was washed with ether, and then afforded *d, purified narcotine.* Under *c*, the difference between *a* and *b*, representing the amount of *waxy matter*, is calculated. It includes also the oily matter, with which the Persian opium, No. IX, is impregnated, as well as a little wax in the case of sample I.

In exhausting the opium with ether a slightly yellowish fluid is obtained which displays a *bluish fluorescence*, due to an unknown constituent of the drug.

Before precipitating the morphine, the aqueous solution was concentrated in order to get a smaller volume. It afforded *e*, the *crude, dried morphine*, which, after twice or three times repeated recrystallization, finally furnished *f, purified morphine.* This purification of morphine cannot be performed without a loss of morphine; the real practical percentage of that alkaloid may therefore more correctly be regarded as somewhat superior to the figures *f.* It would be desirable to apply a process furnishing the exact percentage; yet there is, as far as I know, no such method thoroughly satisfactory. I have been struck with the very large discrepancy, in the Indian opium, of the figures under *e* and *f*, which I think is larger than in opium from Asia Minor. Another fact well worth considering is the usually low percentage of morphine of Indian opium, narcotine being frequently present to a larger amount. This has already been pointed out in the 'Pharmacographia,' p. 57. It would appear, however, that this is of no consequence for the Chinese consumption, yet possibly it will be so some day if the home production of the Chinese further increases. Perhaps a more careful preparation of the Indian opium would at least prove of importance, not so much with regard to the smokers of the drug as to the possibility of extracting morphine from Indian opium profitably It is not needful to point out that this would be highly desirable.

The results of the analyses just mentioned are the following:—

	I.		III.	IV.	V.	VI.	VII.	VIII.	IX.	X.	XI.	XII.
a. Ethereal extract, *i.e.*, residue dried after the evaporation of the ether...	24·2	21·7	22·0	20·6	14·1	17·4	20·4	——	25·0	23·7	18·1	23·6
b. Crude *narcotine*....	10·0	9·0	8·5	7·6	7·6	8·0	9·7	——	10·2	12·2	9·3	11·6
c. Wax; difference between *a* and *b*...	14·2	12·7	13·5	13·0	6·5	9·4	10·7		14·8	11·5	8·8	12·0
d. Purified *narcotine.*	4·0	6·1	5·5	4·5	4·7	3·1	5·4	7·7	6·4	8·7	6·0	8·1
e. Crude *morphine*....	11·2	11·2	14·1	10·6	14·4	——	——	——	——	——	——	——
f. Purified *morphine*..	8·6	4·3	3·5	4·6	6·1	3·8	3·2	6·07	7·1	5·8	4·3	8·3

A NEW METHOD OF MAKING SUPPOSITORIES, MEDICATED PESSARIES, AND BOUGIES.

BY ALEXANDER ELLIS, A.P.S.

To the dispenser of medicines the making of the above articles has always been a bugbear. Even if he possess a supply of proper moulds it is more than probable it will prove of little value unless it include every conceivable size. Prescribers are not bound by any law in regulating the size of these articles, although the amount of active ingredient may vary little.

Several different plans have been advocated for making these articles. Thus we have the metal mould, a machine not possessed by every dispenser. Mr. Procter, in his 'Lectures on Practical Pharmacy,' gives directions for extemporizing moulds of tin foil. I have tried this method, but not with unvarying success, as on one occasion, during frosty weather, I had the misfortune to break my minim measure on pressing the hot sealing-wax into it. Mr. Procter forgets to state what size the cones should be made, so that it is almost impossible to divide the quantity of ingredients evenly between each mould.

In the *Pharmaceutical Journal* of the 27th February, I find an extract from a paper read before the Philadelphia College of Pharmacy by Mr. George W. Kennedy, on "Suppositories." This gentleman, whilst condemning the practice of using moulds or of buying suppositories from the wholesale druggists (as not being reliable for the equal distribution of the medicaments) offers a new method for making them which I think to be a very *dirty* and impracticable one, especially to any one who suffers from hot hands. Suppositories containing half their weight of ung. hyd. mit. or ung. hyd. nit. mit., which are now frequently prescribed, could not be made by the process recommended by this gentleman.

Now, there is no reason why anyone may not turn out suppositories, pessaries, or bougies *cleanly* and *expeditiously*, at a moment's notice, without the aid of a metal mould, or soiling the fingers, if the following directions be attended to. I have practised the mode for some time now; it has always given satisfaction, and I am in no dread of suppositories being required at any time or of any size.

Take a sheet of moderately stiff *glazed* paper (note paper will do, if of good quality), cut it into pieces of about three inches square. Pieces of less size will do if the operator can form cones with them, but for all ordinary purposes three-inch squares will be found the most convenient to work with. Taking hold of these squares between the forefinger and thumb of each hand turn them into cones precisely as a grocer would make a sugar-paper, being particular to twist the bottom evenly and tightly. Now cut the top off evenly with a pair of scissors, so that the cone for 15-grain suppositories will measure one inch in length inside, the diameter at the top being three-eighths of an inch, and for pessaries of one drachm, one inch and three-eighths deep, diameter, three-fourths of an inch. Fill these cones with water and insert them into the mouths of one-ounce phials; let the water remain in them for a couple of minutes, when they may be emptied; they are then fit to receive the ingredients of the suppository. During the time the moulds are being folded and prepared the cacao butter can be gently melted. Allow it to cool until it becomes of a creamy consistence, or so as it will run. Stir in the active ingredient which has previously been rubbed up on a slab with a little oil, glycerine, or lard, such as its nature requires; then pour into the moulds, using a glass rod to direct the stream, and stirring between each filling. In two or three minutes the suppositories will be sufficiently hard to be transferred, with the paper mould still on them, to a mortar full or a stream of cold water. Let them remain there for about five minutes, or less in cold weather, when they can be taken up and the paper easily detached, commencing by unfolding the bottom of the cone. The suppositories will turn out perfectly formed, with perhaps the least fringe at the top which may be pared off with a pocket-knife.

I have lately had to make rods one and a half inch long by one-third of an inch in diameter, as prescribed by Dr. Tanner in his 'Practice of Medicine.' These may be made by taking the same kind of paper as used for suppository moulds, but about eight inches square; roll it on the counter to the required diameter, something like a cartridge mould. Tie it with shop twine in the middle and at each end. Seal up one end with sealing-wax and insert it into an eight-ounce bottle, letting it pass to the bottom. Any number of these moulds may be made at a time. Now, proceed as directed for suppositories, and when the rods are sufficiently hardened, cut the twine, place them on a slab, when the paper can be easily unrolled from them, and the rods cut into the required lengths.

I quite agree with Mr. Kennedy in stating that the best excipient for suppositories is cacao butter. No other substance, possessing the same consistence when cold, will melt at the low temperature this will, and it is of importance that suppositories or pessaries should do their work quickly without the chance of remaining whole and causing irritation when used, or of being expelled after some hours in the same condition as when administered. But attention should be paid to the fact of the cacao butter being pure and not mixed with animal fat; that, in fact, it answers to the characters given it in the British Pharmacopœia. Should this be so the dispenser need not fear preparing a few suppositories for stock even in hot weather.

Skelton-in-Cleveland, March, 1875.

THE INFLUENCE OF BORAX UPON FERMENTATION AND PUTREFACTION.*

BY J. B. SCHNETZLER.

During the discussion which has taken place in the French Academy between MM. Pasteur and Fremy upon the theory of fermentation, M. Dumas intervened, and pointed out that there are two kinds of ferments: those which live and multiply during fermentation, of which beer yeast is the type, and those which destroy during their action, of which diastase is the type. In reserving the name of fermentation to the chemical action produced by the ferments of the first type, M. Dumas arrived at the conclusion that fermentation is a chemical phenomenon accomplished under the necessary influence of the life of the yeast. After having studied the action of a large number of substances upon yeast, he investigated the properties of borax. He found that this body coagulated yeast, dissolved the membranes which remained suspended in an unfiltered solution of white of egg, prevented the interversion of sugar by yeast water, arrested the action of diastase, and paralysed synaptase. This communication was the point of departure for the following experiments and observations by M. Schnetzler:—

(1) *Action of Borax upon the Protoplasm of Vegetable Cells.*—(*a*) Leaves of *Elodea canadensis*, in the cells of which the protoplasm presents an easily observed rotatory movement, were plunged into a concentrated solution of borax. The plasmatic current continued for some minutes, then slackened and stopped completely. The protoplasm contracted, receded from the cell-wall, and condensed into one or two rounded masses containing grains of chlorophyll. The living matter of the cell had been killed by the borax.

(*b*) When fresh leaves of *Vaucheria clavata* were plunged intact into a concentrated solution of borax, the protoplasm was coagulated and receded from the cell-wall, which became perfectly transparent. The globules of chlorophyll were contracted and recurved, becoming crescent-shaped. When the spores of *Vaucheria* are transferred from the mother cell into water they execute some rapid movements by the aid of small vibratory hairs. In a solution of borax these movements were almost immediately arrested; the protoplasm of the spore contracted

* Abstracted from the *Comptes Rendus*, vol. lxxx., p. 473.

and was transformed into a finely granular mass in the interior of the cell.

In a similar manner borax produced coagulation of the protoplasm in the spores of *Oïdium Tuckeri* (the grape fungus), in the cells of yeast, moulds, etc.

(2) *Action of Borax upon the Animal Organism.*—(*a*) Infusoria, rotifera, and entomostraca, placed in water containing borax quickly ceased to move, and then died; the contraction and coagulation of the sarcode of the infusoria being distinctly perceptible.

(*b*) The larvæ of frogs, rendered transparent by prolonged keeping in obscurity, when placed in the solution of borax manifested convulsive contractions in the muscular fibres of the tail. The circulation of the blood slackened gradually, the plasma of the blood coagulated, and in less than an hour death took place.

The preceding observations showed that borax caused a cessation of the properties by which the life of vegetable and animal protoplasm is manifested. If, therefore, fermentation is a chemical phenomenon, accomplished under the influence of the life of the yeast, borax ought necessarily to act antagonistically to fermentation. To test the correctness of this inference some experiments were made upon the—

(3) *Action of Borax upon Fermentescible Matters.*—(*a*) In October, 1872, some very ripe single grapes were placed in a concentrated solution of borax, together with an entire bunch, and kept in a closed vessel. The liquid, at first colourless, became slightly brown; but both the single berries and the entire bunch, presented after two years the same appearance, whilst there was no trace of fermentation. Although, however, the grapes were well preserved, they were not eatable. Diffusion had taken place: a great part of the sugar had passed through the skin of the grape, whilst the borax had penetrated to the interior where it had coagulated the albuminous matter of the cells. The same result was obtained with currants. When the flasks were well closed no trace of mould was seen; but when the air had either free or limited access, a mould (*mucor*) was formed, without fermentation, accompanied by disengagement of gas. When, as a counter test, grapes were placed in a well-closed vessel filled with ordinary water, after a time, according to the temperature, fermentation took place, with evolution of carbonic acid.

(*b*) Thirty cubic centimetres of fresh milk were placed in a test tube with 1 gram of borax. The cream quickly formed a rather thick layer in the upper portion. Notwithstanding the test tube was closed by a cork, a mould was formed upon the cream; but the remainder of the liquid underwent no acid fermentation, and retained during several months the appearance of very clear creamed milk. Afterwards, under the influence of summer heat the liquid became perfectly limpid, and deposited the casein as a soft white matter; but neither the deposit nor the liquid had an acid taste, and after three months they still had the odour of fresh milk. Fresh milk put into a well closed test tube without borax underwent acid fermentation in from two to three days, and became thick by coagulation of the casein.

(*c*) A piece of sheep's brain was powdered with borax. Eight days afterwards it gave off a spermatic odour; later there was a disengagement of sulphuretted hydrogen without any appearance of putrefaction properly so-called. The matter after retaining a soft consistence during several months became hard, and almost horny, without any disagreeable odour.

(*d*) A pound of beef was placed in a concentrated solution of borax, in a tin case not hermetically closed. The colouring matter of the blood diffused into the surrounding liquid as well as a portion of the soluble nitrogenous substance of the meat. After some weeks the liquid assumed a brown colour and gave off a rather disagreeable odour without any putrefaction of the meat. When the liquid was removed and the meat washed with cold water it had an odour *sui generis*, but having no similarity to that of putrefying meat. After a year and a half, notwithstanding the heat of the summers of 1873 and 1874, this meat—the surrounding liquid having been renewed three times—had not the least odour of putrefaction. It was of a yellowish colour, but as soft and tender as fresh meat. Removed from the borax solution the meat remained in the same state in the air.

(*e*) Beef, veal, and portions of sheep's brain were placed in a vessel which was filled with solution of borax and hermetically sealed. The liquid soon became clear red, and this colour remained during several months without alteration. The meat presented not the least disagreeable smell as long as access of air was prevented. Meat placed in water in a flask hermetically sealed became rotten in a few days.

The peculiar odour of meat preserved in borax in contact with air the author considers to be due to the decomposition of matters which result from the metamorphosis of substances that constitute the muscular and intermuscular fibre. Although probably the use of borax will not be applicable to the preservation of meat for culinary purposes, the author considers that it may be economically substituted for alcohol in the preservation of anatomical specimens. Moreover, its power of suspending life in the lower organisms would seem to indicate its probable utilization in the treatment of wounds, etc.

NEUTRAL HYDROBROMATE OF ESERINE.*

BY M. DUQUESNEL.

Eserine, the active principle of the Calabar bean, is an alkaloid discovered by Vée, which combines readily with acids. The salts that it forms are generally uncrystallizable and very hygroscopic. An exception to this rule however has been met with in the hydrobromate of eserine, which has been recently brought under the notice of the French Academy of Medicine by the author.

The best known of the salts of eserine is the neutral sulphate frequently employed by oculists. It occurs under the form of a yellowish—sometimes red—mass; but it may be obtained colourless by preventing completely the oxidizing action of the air, which converts the eserine into a red crystallizable, but inert, substance. In the amorphous state the sulphate appears to be present as a supersaturated solution; for if left to itself, stellate groups of acicular crystals are sometimes formed by the absorption from the atmosphere of a small quantity of moisture.

After employing several acids—hydrochloric, oxalic, etc.—without obtaining any better results than with sulphuric acid, the author employed hydrobromic acid, which yielded slowly, but regularly, stellate groups of crystals and a fibrous crystalline crust. The product was slightly coloured, but M. Duquesnel hopes in further experiments to obtain the salt nearly white. Meanwhile the present product yields almost colourless solutions, especially if boiling distilled water be used, with a slight addition of glycerine, which ensures the preservation of the solution.

The advantages claimed by the author for the new salt are its crystallizability, its perfect solubility in water, in which it forms a neutral solution, and that it can be preserved perfectly even in a humid atmosphere. It contracts the pupils as well as the other salts of eserine.

THE ACTIVE PINCIPLES OF THE OFFICINAL VERATRUMS.†

A. CHEMICO-PHYSIOLOGICAL STUDY.

BY CHARLES L. MITCHELL.

PART II.—CHEMICAL.

(*Continued from page* 787.)

The quantity of alkaloids in veratrum album varies quite as much as in veratrum viride; from two different lots I obtained the following results:—

* *Répertoire de Pharmacie*, [N.S.], vol. iii., p. 105.

† Read before the American Pharmaceutical Association. Reprinted from the 'Transactions.'

In One Pound Avoirdupois (7000 grains.)		No. 1.	No. 2.
Alkaloid soluble in ether	grs.	40·50	30·3
Jervia	,,	11	8
Resin	,,	240	200
Oily matter	,,	144	105

The alkaloid soluble in ether resembles very much the veratrum viride alkaloid veratroidia. It is white, uncrystallizable, of a bitter, acrid taste, leaving a burning, tingling sensation in the fauces, even more acrid and irritating than veratroidia, and produces the most violent sneezing. It is soluble in alcohol, amylic alcohol, ether, chloroform, carbon bisulphide, and sparingly in benzin. It forms with the acids soluble salts, which are uncrystallizable. It fuses at 340°, and sublimes in small feathery crystals. The alkalies and their carbonates precipitate it from its acid solutions in white, semi-crystalline flakes, which are slightly soluble in an excess of the precipitant, especially when ammonia is used. With the bicarbonates it yields a precipitate only on heating.

The jervia corresponds chemically to that from veratrum viride. All these alkaloids are precipitated from their solutions in tartaric acid by bicarbonate of soda. Their behaviour with colour reagents is seen in the following table as compared with veratria.

Reagent.	Jervia.	Veratroidia.	Veratria.	Alk. Verat. Album (Veratralbia.)
Sulphuric Acid.	Yellow, changing to a deep green.	Yellow, changing to a brick-red.	Yellow, changing to a crimson.	Yellow, changing to a rich, dark-red.
Sulph. Acid and Br.	Changes from green to a very light brown colour, almost colourless.	Brown.	Brick-red.	Dark-brown.
Sulphuric Acid and Chromate Potass.	Yellowish-brown.	Brown.	Brown.	Brown.
Hydrochloric Acid (cold)	Diss. to a colourless solution.	Diss. to a colourless solution.	Diss. to a colourless solution.	Diss. to a colourless solution.
Hydrochloric Acid (hot)	Yellow, deepened by boiling.	Yellow, deepened by boiling.	Yellow, when boiled changing to a deep solferino colour. (*Trappe's Test.*)	Yellow, deepened by boiling.
Nitric Acid.	Yellow, deepened by boiling.	Yellow, deepened by boiling.	Yellow, deepened by boiling.	Yellow, depeened by boiling.
Percholor. Gold.	Curdy yellow ppt.	Yellowish white ppt.	Yellow-white ppt.	Straw-yellow ppt.
Iodohyd. Potass.	Curdy white ppt.	White ppt.	White ppt.	White ppt.
Bichlor. Plat.	Gran. yellow ppt.	Flocc. yellow ppt.	Very faint ppt.	No reaction.
Sulphocyan. Potass.	Flocc. white ppt.	White ppt.	White ppt.	White ppt.
Chlorine Water.	Faint whittish ppt.	White ppt., faint.	White ppt., faint.	White ppt., faint.
Tannic Acid.	White.	White ppt., faint.	White ppt. faint.	White ppt., faint.

We thus see that this alkaloid from veratrum album differs from both veratria and veratroidia. It is, I think, a distinct principle, as will be further shown by its physiological action. It is much more powerful than either of these alkaloids. For this principle I propose provisionally the title of veratralbia.

Dr. Peugnet's resin proved pretty conclusively that dilute acetic acid would not exhaust the root; I tried a small experiment with the same menstruum and came to the same conclusion.

The question of the profitable extraction of the alkaloids from veratrum viride and veratrum album, is a matter of considerable uncertainty, and I doubt very much if they can ever be brought into extended use. They exist in extremely small proportion, and their separation is attended with so much difficulty and expense, that I think it extremely unlikely their manufacture on a large scale will ever be attended with success.

SABADILLA.

Four pounds of finely ground sabadilla seeds were exhausted by percolation with alcohol 85 per cent., the alcoholic tincture evaporated to a small bulk, acidulated with 4 fluid ounces of acetic acid, and poured with constant stirring into 4 gallons of distilled water. The acid liquid was evaporated to 2 pints; the separated resin being mixed with that first precipitated, dissolved in 2 pints of alcohol, and set on one side. Milk of lime in excess was added to the concentrated acid liquid, the whole allowed to stand twenty-four hours, and then filtered, and the precipitate well washed, drained and dried. This was powdered, mixed with some animal charcoal, and then the whole mass repeatedly digested with strong alcohol, until nothing more was dissolved. The alcoholic solution was evaporated to dryness, and the resulting resinous mass dissolved with gentle heat in dilute sulphuric acid, concentrated to a small bulk, and set aside to deposit jervia. After the lapse of some days, the liquid still remained perfectly clear, showing that it contained no jervia. It was now decolorized by boiling with a little pure animal charcoal, a little alcohol added, and then precipitated with an excess of sol. soda. The precipitate when washed and dried weighed 840 grains. This was agitated with successive portions of ether, and the ethereal solution shaken frequently with dilute sulphuric acid, the heavier liquid separated, warmed slightly to free it from ether, and then precipitated with sol. soda, washed and dried. It weighed 800 grains, was quite white, and corresponded to veratria in its reactions.

The residue remaining from the ether was boiled with distilled water, the insoluble portion filtered off, and the filtrate concentrated and set to one side, to see if it would crystallize; the residue on the filter was treated with dilute sulphuric acid. This partly dissolved it, the insoluble portion being resin. This soluble resinous matter corresponded to Couerbe's "Le Veratrin," being insoluble in ether, soluble in acids, and precipitated by alkalies. On adding ether to this solution, then, excess of soda, and agitating, the precipitate at first formed was nearly all dissolved, there remaining only a small portion of resinous matter adhering to the sides of the bottle. The ethereal solution was removed, and the heavier liquid acidulated with sulphuric acid, which now only partially dissolved the resinous matter. The insoluble portion was separated, and as I found the solution still gave a precipitate, it was again treated in the same manner. The precipitate this time was nearly all taken up by the ether, only a little resinous matter remaining. When this was treated with the acid it did not dissolve, and the liquid gave no precipitate with an alkali. The different insoluble portions filtered out were found to be resin. The ethereal solutions were mixed, and the alkaloid extracted; it weighed 30 grains, and chemically and physiologically proved to be veratria. I therefore conclude that Couerbe's "Le Veratrin" was only an intimate mixture of resin and veratria.

The liquid which was set aside gave a small quantity of crystals, which answered to all Hübschmann's tests for sabadillia. The quantity was too small to admit of any physiological experimentation.

(*To be continued.*)

The Pharmaceutical Journal.

SATURDAY, APRIL 24, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE GLASGOW MEMORIAL.

WE regret that it is again necessary for us to refer to this subject, but the nature of several of the communications that have reached us from Scotland leaves no alternative.

As regards the official disclaimer of the Scotch examiners that they had any cognizance of what was going on in Glasgow, it will probably suffice to call the attention of our readers to the letters that appear in this number from Mr. TAIT, the Chairman of the Board, and from Mr. GILMOUR. The same course may be taken in regard to the letter of Mr. MACKAY, which is to the same effect, and we must leave our Edinburgh and Glasgow friends to settle amongst themselves an explanation of the contradictory impressions under which they have been acting.

Judging from what took place at the April Council meeting, when the memorial was read, there was ample ground for the surprise we then felt constrained to express at the absence of communication between the Glasgow Association and the executive of the North British Branch of the Society. Mr. MACKAY not only stated that the Board in Edinburgh had not the least idea of the feeling represented by the memorial as existing in the minds of the Glasgow chemists and druggists, but he also disavowed any knowledge that they were holding meetings for the purpose of producing such a memorial. He even went so far as to suggest by implication that there was no real ground for the production of such a memorial, for in remarking that the Edinburgh Board would gladly have waited on the Glasgow Association to discuss the grievances supposed to exist, he added that the probable result of such a course would have been to prevent the presentation of the memorial.

We consider it as signally unfortunate, at least, that no communication took place between these bodies sufficient to ensure a thorough consideration of the matter by them before it was brought under the notice of the London Council. Considering that there is a Branch of the Society established in Scotland, it seems only natural that matters having, as it seems, a purely local significance, should be dealt with by that Branch, and it is much to be regretted that the disregard of this appropriate official routine should have resulted in causing some degree of antagonism and embarrassment.

In addition to what we have already said of the memorial itself, and of the explanatory note of Mr. CURRIE and Mr. FAIRLIE, we must confess that the further explanations Mr. FRAZER sends for publication this week, as well as other communications on the subject, only tend to confirm our feeling of surprise that the memorial should have been presented at all. According to Mr. FRAZER's own statements we cannot perceive that he recognizes any adequate reason for such a course, or indeed any pretext for it beyond a vague belief that the nature of the examination regulations and the difficulty of getting assistants in the West of Scotland stand in the relation of cause and effect. Our own estimate of this belief leads us to regard it not only as a delusion, but as a proceeding calculated to exercise a very mischievous influence at the present time, when the value and beneficial influence of the examinations are just beginning to be acknowledged.

Under these circumstances we cannot recognize the justice of Mr. FRAZER's objection to our remarks on the memorial. By its publication it had become open to criticism, and that being the case we cannot perceive any reason for delaying such criticism for a month. But Mr. FRAZER's objection is, in itself, an evidence of weakness, and it throws a doubt upon the existence of any reasonable grounds for the course that has been taken by the Glasgow Chemists and Druggists' Association. According to our observation it is now generally the custom, when the desirability of a thing is felt, to seek the publicity of the press as the best and most efficient means of evoking opinions that are latent in the minds of many, but which without some such stimulus would remain unexpressed. One would be disposed to expect that the announcement of a memorial to the Council on the subject of a keenly felt difficulty would have called forth communications from many of those who experienced the difficulty complained of, and that they would have been eager to bring forward facts illustrative of the particular inconveniences they suffered, as well as evidence to show that their view of the causes whence they arose was correct. Such a discussion of any subject in regard to which the Council of the Society had been memorialized would, we imagine, have conduced towards strengthening the position of those who supported the prayer of the memorial whenever it came to be a matter for the Council to decide upon what measures should be taken.

Our remarks afforded opportunity for such discussion, and for that reason alone we consider that they do not merit the condemnation of being either unwise or ungenerous. That the tendency of our remarks should have been unfavourable to the memorial and its objects is a circumstance that we cannot seek to excuse otherwise than by pleading a general regard to the fitness of things. And if we look to the correspondence that has reached us on the memorial there is ample confirmation for the opinion we expressed at first concerning the unsatisfactory state of affairs in the West of Scotland. It seems that while the feeling manifested by the writers is all in one direction, it does support the hypothesis as to the dearth of assistants being referable to the examination in any way.

Mr. KINNINMONT'S letter strongly supports the opinion suggested by the memorial itself, and by all the proceedings we have become acquainted with in reference to it, that the Glasgow Chemists and Druggists' Association has allowed itself to be led away by misconceptions as to the real causes of the evils it complains of. Thus regarded, the discussion of this matter may, we hope, prove to be beneficial to all concerned.

UNUSUAL DOSES OF POTENT DRUGS.

THE question of the advisibility of adopting one recognized method of indicating to the dispenser when an unusually large dose of a powerful ingredient is ordered in a prescription, that is not through an oversight of the prescriber, has recently been under the consideration of the Academy of Medicine and of the Pharmaceutical Association of Richmond, in the United States. It will be remembered that in this country the subject was brought forward at the meeting of the British Pharmaceutical Conference at Bradford in 1873, by Mr. HAMPSON, when the result was the adoption of a report recommending that in prescriptions, after any unusual dose, the prescriber's initials, between brackets, should be placed, and that this recommendation was communicated to the medical profession. A joint committee of the above-mentioned American Societies has, however, reported in favour of the use in such cases of the letters *p. c.* (*prœter consuetudinem*), and this recommendation was adopted at a meeting of the Richmond Academy of Medicine. Another suggestion that the members of both Societies should use every proper means to limit the sale of such drugs as opium and chloral, and a third to the effect that the dispenser should not be considered at liberty to reveal to the patient the components of a physician's prescription written in technical language, were also concurred in. But a recommendation to substitute the use of the Greek Δ for the sign ℨ in order to avoid confusion with the sign ℥, was overruled by a majority of votes.

PERSONATION OF CANDIDATES OF APOTHECARIES' HALL.

IN a letter to the *Medical Times and Gazette* Mr. R. H. ROBERTSON, the Secretary to the Court of Examiners in Arts of Apothecaries' Hall, London, describes what appears to have been a gross case of fraudulently obtaining a certificate by a personation of the candidate. It appears that at the top of the first class of the pass list of the usual examination in Arts, held at the Hall in January last, was placed the name of CHARLES MATTHIAS LAMB, and the certificate was forwarded in due course. Information was afterwards received, however, which gave rise to the suspicion that CHARLES MATTHIAS LAMB had not been present himself at the examination, but that he had been personated by somebody else, who answered the examination papers for him. These suspicions were communicated to Mr. LAMB, accompanied by a demand that the certificate should be returned to be cancelled, as improperly obtained. Their correctness was confirmed by the return of the certificate on the following day, and the Society therefore thinks it desirable that the circumstances should be generally known. We are of opinion our contemporary is quite justified in asking whether Mr. ROBERTSON'S duty ends here, and whether no other steps are to be taken.

THE ACTIVE PRINCIPLES OF JABORANDI.

WE have received from Mr. A. W. GERRARD, too late for insertion in this number of the Journal, a paper describing the method adopted by him in separating what he considers to be an alkaloidal principle representing the active constituent of Jaborandi (*Pilocarpus pennatifolius*), an opinion which appears to be confirmed by the results of some physiological experiments made under the supervision of Dr. SIDNEY RINGER.

COD LIVER OIL BREAD.

COD Liver Oil Bread, which has on more than one occasion been noticed in these columns, has recently formed the subject of a lawsuit in France. A firm of bakers, by whom it had for some years been made, claimed a monopoly of its manufacture in virtue of a patent held by them. This was disputed, amongst others by a pharmacien, and the cause came on for hearing a few days since. The Court decided that the invention could not form the subject of a patent, in that it was not a simple alimentary product, but a medicament. The suit was therefore dismissed with costs against the bakers.

THE SALE OF VERMIN KILLERS.

IT would appear from the fact that we are in receipt of several communications respecting the sale of vermin killers that there still exists a considerable amount of misapprehension as to the conditions under which they can legally be sold. In consequence of the pressure upon our space we are compelled to defer dealing with these communications until next week.

THE ANNUAL DINNER.

WE are requested to state that a list of the names of the gentlemen who have expressed their willingness to act as Stewards on the occasion of the Fourth Annual Dinner of the Pharmaceutical Society and their friends will be published next week. The Honorary Secretaries would, therefore, be glad to hear at once from any gentleman who may desire to have his name included, but who has not yet communicated to them his wish to that effect.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

April 21st and 22nd, 1875.

Present—(21st) Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Hills, Linford, Martindale, Moss, Schweitzer, Southall, Taylor, and Umney.

(22nd) Messrs. Allchin, Barnes, Benger, Bottle, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Southall, Taylor, and Umney.

MAJOR EXAMINATION.

Ten candidates were examined. *Two* failed. The following *eight* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

	Holt, George Alfred	Douglas.
Equal	Broad, John Morris	Hornsey.
	Harrington, Arthur	Needham Market.
Equal	Lambert, William Henry	Hull.
	Llewellyn, John	Cowbridge.
	Worthington, William	Preston.
	Newhill, John William	Huddersfield.
	Blackwell, Josiah	St. Austell.

MINOR EXAMINATION.

Thirty-nine candidates were examined. *Sixteen* failed. The following *twenty-three* passed, and were declared qualified to be registered as Chemists and Druggists:—

	Ellis, Henry	Rochdale.
	Folkard, Montague	Colchester.
	Saville, George	Wakefield.
	Clarke, Isabella Skinner	Paddington.
	Mackay, Edward	Masham.
	Highmoor, George Samuel	Leeds.
	White, Charles	Southborough.
Equal	Dodd, William Henry	Fulham.
	Leece, Frederick	Preston.
	Butler, James Arthur	Leicester.
	Metzler, Heinrich J. C. L.	London.
	Widdowson, William	Nottingham.
Equal	Cocker, Justus John	Over Darwen.
	Martin, Henry Stephen	Brighton.
	Clegg, Edmund	Manchester.
	Beale, James Hawkins Tizard	Camben Town.
Equal	Phillips, James Arthur	Penge.
	Vaughan, John	Newtown.
	Cant, Hemington	Stratford.
	Spilsbury, James	Stafford.
Equal	Brown, Frederick	Lincoln.
	Slater, Thomas, jun.	Stone.
	Senier, Alfred, jun.	Finsbury Park.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's Examination:—

Certificates of the College of Preceptors.

Gowing, George D. .... Faversham.
Hodgkinson, William E. ....

Certificate of the Royal College of Surgeons.

Womack, Frederick .... Bayswater.

Certificate of the University of Cambridge.

Kirk, William Peele .... Retford.

Certificate of the University of Durham.

Hunter, Frederick William...... Newbottle.

PRELIMINARY EXAMINATION.

ENGLAND AND WALES.

April 5, 1875.

One hundred and eighty-eight candidates presented themselves for examination, of whom *ninety-six* failed. The following *ninety-two* passed, and have been duly registered as Apprentices or Students:—

	*Parker, Charles Henry Mitchell	South Molton.
	*Stroud, Henry	Bristol.
	*Stone, Frederick William Stanley	Bristol.
Equal.	*Hopkins, William Richard	Aberystwith.
	*Smith, John	Crownthorpe.
	*Madden, Ronald George	London.
Equal.	*Chambres, Charles	Denbigh.
	*Cooper, Henry Scarborough	Grantham.
	*Foster, Ferdinand Green	Landport.
	McDonald, John	Liverpool.
	Heywood, Frederick	Manchester.
Equal.	Butler, Christie H.	Tooting.
	Maddocks, William	London.
	Marshall, Daniel	Shrewsbury.
	Adams, Joseph	Bristol.
	Lusby, Absalom	Louth.
Equal.	Gordon, Thomas Elisha	Swansea.
	Hornby, Alfred	London.
	Pavey, Henry John	London.
	Phipps, Frederic	Birmingham.
	Wallbridge, Henry Alfred	London.
Equal.	Cooper, Henry Samuel	Droitwich.
	Jeffreys, John Alfred	Levenshulme.
	Jones, Frank	Fairfield.
	Norris, Alfred Beardmore	London.
	Price, Frederick	Liverpool.
	Stevenson, John Joseph	London.
Equal.	Edmond, Francis Edward	Scarborough.
	Jones, Joseph Humphrey	Wolverhampton.
	Lubbock, John William	London.
	Moore, William Glover	Liverpool.
	Whitaker, Thomas	London.
	Wignall, Walter	York.
Equal	Garrett, John Henry	Notting Hill.
	Jacklin, Alfred	Louth.
Equal.	Ball, William Benjamin	Abingdon.
	Brown, Joseph	Walker-on-Tyne.
	Mordue, William	Haydon Bridge.
	Ninnis, Thomas Martin	Truro.
	White, John	Bristol.
	Duncan, Alexander	London.
Equal.	Knight, Charles	Gloucester.
	Webb, William Henry	Hereford.
Equal	Baker, Henry William Burgess	Haddenham.
	Davies, Frank	Newcastle Emlyn.
Equal.	Berry, Thomas Samuel	Northampton.
	Blades, Arthur Mowbray	Northwich.
	Chapman, William Henry	Birmingham.
	Fox, Richard	Norwich.
	Randall, William Joseph	Wareham.
Equal.	Beard, James Hogg	Manchester.
	Bottomley, Albert Frederic	Halifax.
	Bryant, Richard William	Swansea.
	Fox, Alfred	Hull.
	Gratte, Alfred	Newport, Mon.
	Green, William Travis Nunn	Liverpool.
	Jepson, Xeno	Sheffield.
	Merrell, Arthur James	London.
	Newman, Alfred Pointon	Crewe.
	Mason, Florus	Broughton.
Equal.	Critchlow, Henry	Oldham.
	Moor, George	Grantham.
	Wingrave, Arthur	Coventry.
	Llewellyn, Thomas	Pembroke.

* Passed in the First Division.

Equal.
Batty, Edward ....Ilkley.
Bayley, Cornelius ....Boston.
Botwood, Charles Walker ......Great Bridge.
Brooks, John.........................Poplar.
Cocksedge, George Bloomfield London.

West, William Painter ....Liskeard.
Whittaker, Joseph ....Salford.
Wood, Francis Wilson ....Sheffield.

SCOTLAND.

Thirty-four candidates presented themselves for examination. Of these *twelve* failed. The following *twenty-two* passed, and have been duly registered :—

*Robertson, Alexander ....Broughty Ferry.
*Whyte, James Samson ....Glasgow.
*Brown, David Matthew.........Dunfermline.
*Waddell, William ....Belfast.
*Symington, Archibald ....Helensburgh.
*Mackay, Alexander ....Aberdeen.
*Patterson, William...............Canonbie.
*Runciman, Wm. Morrison......Kelso.
*Morison, John......................Edinburgh.
Bruce, William Balfour ....Kirkwall.
Equal. { Halley, John Milne ....Edinburgh.
Thomson, William..................Aberdeen. }
Equal. { Stewart, Alexander Reid ....Hamilton.
Thomson, John Francis ....Edinburgh. }
McNeilage, Alexander............Greenock.
Burrell, Thomas ....Montrose.
Mackenzie, Donald ....Dingwall.
McDonald, Alexander Minto ...Edinburgh.
McDonald, Robert ....Edinburgh.
Grant, James.........................Aberdeen.
McIntyre, John ....Edinburgh.
Young, James ....Dumbarton.

The questions for examination were as follows :—

Time allowed : Three hours.

LATIN.

Cæsar—De Bello Gallico, Lib. I.

1. Translate into English :—His Cæsar ita respondit : Eo sibi minus dubitationis dari, quod eas res, quas legati Helvetii commemorâssent, memoriâ teneret : atque eo gravius ferre, quo minus merito populi Romani accidissent ; qui si alicujus injuriae sibi conscius fuisset, non fuisse difficile cavere : sed eo deceptum, quod neque commissum a se intelligeret, quare timeret ; neque sine causâ timendum putaret. Quod si veteris contumeliae oblivisci vellet ; num etiam recentium injuriarum, quod eo invito, iter per Provinciam per vim tentâssent, quod Aeduos, quod Ambarros, quod Allobrogas vexâssent, memoriam deponere posse?

* Passed in the First Division.

Grammatical questions on the preceding passage.

2. Compare *minus, veteris.*

3. Give the principal tenses of *dari, ferre, cavere oblivisci, posse.*

4. Explain the case of *quas, memoriâ, sibi, iter, invito.*

ARITHMETIC.

5. Multiply six hundred and fifty thousand and ninety, by three thousand and eight ; also seventy-six millions, eight thousand, seven hundred and sixty-five, by nine millions, nine thousand and nine.

6. Multiply $\frac{1}{2}$ of $\frac{2}{3}$ by $5\frac{3}{8}$ of 3, and divide $4\frac{1}{3}$ by $2\frac{3}{4}$.

7. Convert $\frac{3}{512}$ and $\frac{3}{51200}$ into decimals.

8. Reduce 4*s*. $7\frac{1}{2}$*d*. to the decimal of £1 ; and 15*s*. $11\frac{1}{4}$*d*. to the decimal of £1.

9. What is the weight in *grammes* of a cubic decimetre of water ? Express the equivalent in *grains* of a decagramme, a centi-gramme, and a milli-gramme.

ENGLISH.

10. Distinguish between transitive and intransitive verbs. Give four examples of each.

11. State the past tense and past participles of the following verbs, *fall, hold, blow, draw, beat, cleave, shake, give, arise, swim.*

12. Write a short sketch of any person celebrated in English history.

The following is a list of the Centres at which the examinations were held, showing the number of Candidates examined at each Centre, and the result :—

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Ninth General Meeting of the session was held at the Royal Institution, March 11. The President, Mr. A. H. Mason, F.C.S., in the chair. Donations of the Calendar of the Pharmaceutical Society, and the *Pharmaceutical Journal*, were received and acknowledged.

Mr. Davies, F.C.S., said that having found a difficulty in detecting small quantities of chlorates in presence of much nitrate and chloride, he had devised a method which had proved very successful. It consists in mixing the dry salts with an equal quantity of dry oxalic acid, and heating gently, preferably in a water bath, in a test tube. Peroxide of chlorine is evolved, and can be recognized by its odour and by the yellow colour on looking down the tube. A mixture of equal parts nitrate and chloride of sodium, with 1 per cent. of potassium chlorate was tested, and gave a decided reaction.

Mr. Murphy, F.C.S., alluded to the Adulteration Act, and said that recently he had tested some green peas, said to contain copper. He found that they only contained 0·008 per cent. of that metal, and he thought to call that an adulteration was absurd, and if so small a quantity could affect the health, something might be said for homœopathy.

Mr. Shaw asked if Mr. Murphy had tested the Liverpool gas lately.

Mr. Murphy said that he tested it at intervals, and found that the illuminating power had increased to 16½ to 17½ candles. In his opinion to use two candles as a standard light and to burn five feet of gas per hour, produced so much glare that no satisfactory results could be obtained, especially with a 60-inch scale. He preferred to use one candle, and to burn only 3 to 3½ feet per hour.

The meeting then adjourned to the Gallery of Arts, where several microscopes were arranged. The President exhibited micro-photographs; Mr. Abraham some injected physiological preparations; and the Secretary specimens of crystallized metallic arsenic and arsenious oxide. Mr. Murphy exhibited a polarizing saccharometer, and showed the manner of using it to determine the strength of a sugar solution. Other objects of interest were also exhibited.

The Tenth General Meeting was held April 8, 1875. The President in the chair.

Donations of the 'Year-Book of Pharmacy,' the *Pharmaceutical Journal*, the *Canadian Pharmaceutical Journal*, and the *American Chemist*, were received and thanks voted to the donors.

Mr. Abraham expressed his pleasure in seeing that Dr. Edwards had been appointed Consulting Chemist to the Board of Inland Revenue of the Dominion of Canada. He looked upon it as an honour to pharmacy and to the Liverpool Chemists' Association.

The President alluded to the same subject, and then called the attention of members to the loss which pharmacy had sustained in the death of Mr. Hanbury. He was an authority to whom was submitted almost every new drug, and his place would be difficult to fill. It was a matter of congratulation that his 'Pharmacographia' was finished before his death. The President also mentioned the warning by the Public Analyst of Liverpool, with reference to the presence of lead in drugs.

Mr. M. Murphy, F.C.S., then read the following

Remarks upon Analytical Processes in Relation to Public and Industrial Requirements.

"I hope there is little necessity to plead the importance and value generally of analytical processes before members of the Chemists' Association. Chemistry, as a branch of physical science, has made considerable progress during the present century, and every day it is growing into greater esteem as well by its own votaries as by the leaders and students in other sciences which appear often desirous to be affiliated with them. Even among the great bulk of the people, who some time ago had only a very hazy notion of what chemistry concerned herself with, and what she was accomplishing in the way of elevating the range of human thought and human pursuits, or who, if they entertained a notion at all, biassed it in the direction of evil spirits and pandemoniac indulgences, contemplating the patient laboratory worker as a monstrosity half human and half fiend—even these are throwing off their superstitious fears of the chemist and gradually making a hopeful estimate of the possible benefit chemical knowledge may extend to them. Now, if we ask ourselves a question respecting the causes which have brought about such results, already very great yet still only in their adolescence, we will come to view them as due almost in a primary degree to analytical processes. I do not wish to undervalue the power of intellect in conceiving and elaborating a train of results in the abstract. Mind so applied is certainly productive of good sometimes, but we must not forget the wonderful fact that notwithstanding such minds have at all times adorned the human race, yet it was not till analytical processes were adopted that chemistry, as an offshoot of former knowledge, made any real progress in opening men's eyes to the conception of the nature of things and endowed society with many benefits.

"The scientific chemist who enters at thought's gate the wide domain of theory cannot securely advance to any great distance undirected by analytical processes.

"Should he decide to ignore or dispense with their guidance and rely on his imagination only I think it might be fairly predicated of such a one that he will soon involve himself in a labyrinth of conflicting relations whence he cannot emerge except indeed he be pioneered by analytical processes.

"I think instances could be given, since Gerhardt propounded his system of nomenclature, to show that many who have essayed the theoretical in relation to the exposition of chemical data have confused rather than simplified the science of chemistry.

"It is not my wish to dwell further on this point; I choose rather to refer briefly to the assistance analytical work and processes have already rendered and are yet likely to render to the physiologist, the pathologist, the agriculturist, and the sanitarian. Taking physiology—without a systematic and studious course of analytical determinations of the quantity and quality of the organs and secretions of the body as well as of the food and drink consumed to sustain life, physiological study would comprise little more than an empirical record of personal sensations. But when we retrace our steps in the way our progress has advanced, and inspect the labours of Boussingault, Mulder, Liebig, Berzelius, Prout, and a cohort of other workers, we are at once impressed by the apparent diligence and assiduity with which each and all endeavoured to establish their conclusions, not on the basis of logical or metaphysical consequence, as was the practice in olden times, but rather on the results of analytical processes applied in direct elucidation of the questions at issue.

"It can readily be understood that when crucial methods of this description were applied to trace the changes of food matter in the animal body, and determine how its constituents, already definitely ascertained, were disposed of in the formation of corporal parts and adjuncts, to be thrown off, after they had done their work, as excreta, the advance to a defined and true system of physiology was inevitable. A similarity of procedure in respect of pathological inquiries has contributed to a definition of the causes of diseases, and defined fairly and broadly the line of treatment that is consistent with the urgency of the case.

"Again, in the important principles involved in agriculture, how much have we gained in the knowledge of the requisite properties of soil by analytical process! And what a cycle of exertion it has required to establish the truth that we must give back to the soil matter in proportion to that abstracted from it by the crop and drainage to maintain it in a proper and suitable condition of fertility! We cannot presume to say that either of these questions has been definitely settled, logically and experimentally, but we are fairly in a position to postulate that we are on the high road to the goal of truth respecting them.

"Viewing the influence of analytical results from a sanitarian's stand-point, what great advantages have been gained! And firstly, as regards the air, a primary necessity of animal existence.

"Till analytical processes determined the true composition of the air and its necessity to the maintenance of healthy animal existence, the only criterion of impurity which the medical man and sanitarian could apply was that of smell. If the smell were bad the air was unhealthy, and contrariwise if there was no cognizable odour the air was esteemed good. Bad odours—*i.e.*, offensive ones—have long been regarded as dubious or prejudicial to health; but I may say that previously to the labours of Dr. Angus Smith, of Manchester, the causes of mischief in a sanitary point of view were not so well defined or explained. Of Dr. Smith's great labours, embodied principally in his work 'Air and Rain,' I may say it appears to me their value does not depend so much upon the mental reach with which he invested the subject, but rather with the care, diligence, and untiring repetitions of analytical process.

"Consequent upon the recognition of the fact that air may become polluted and the proximate cause of endemic diseases, the attention of medical sanitarians was drawn to that of water as the next most important natural necessity of life. Here, again, analytical processes become public health conservators; so much so, that at the present day there is not a municipal body or petty local board that does not seek to know the fitness of the water supply of the district by the agency of analytical processes.

"Finally, the Government of this country, or in other words the outspoken voice of the populace, have determined legislative measures securing the qualities of the food and drink of the people by means of the definitions which analytical processes are able to apply. And taking the general expressions of the community as our determinant, we are forced to the conclusion that the latent benefits which my pet subject, analytical processes, has conferred in this department of its operations are equal to, if not transcending those which they have produced in the spheres already referred to.

"If now we turn to industrial enterprises of a nature to be benefited by analytical processes, what is the first impression that is likely to be made upon any thoughtful mind? It is obvious that there is not one of them wherein complex matters are dissociated or diverse matters conjoined for the purpose of producing useful products, but analytical processes are, so to speak, the presiding genius that leads them to successful results. It would be a difficult task to specify any industry of this order which is indifferent to, or independent of analytical processes. Situated as we are here within easy reach of the chief centre of one of the principal trades of the world—the soda trade—and within close proximity to other large centres of no less important trades—the iron and pottery industries—not to speak of the tinctorial, metallurgical, manurial, and other industries that stud the land, I would be inclined to think that I need only mention the fact of each and all of them being necessitated to subsidize analytical processes to contribute to their being properly and economically conducted to enlist your acquiescence and admit the truth of the proposition without further argument.

"Now, reviewing the great importance that I have attached to analytical processes in the details which I have crudely submitted to you, it must be evident that to reap the full measure of benefit which may possibly be derived in every department from them, it is necessary that they be well conceived in relation to the purposes to which they may be applied, that they be applicable generally, and above all designed so as to afford reliable and trustworthy results. Plainly as I conceive the value of analytical processes, I must not swerve from admitting that much of it is lost in consequence of their varied character and of want of definiteness of their application.

"Whilst a general plan is recognizable among chemists generally, and although in chemical schools a systematic method of procedure is taught for arriving at definite results, we must not overlook the fact that almost every individual chemist engaged in analytical processes builds up his own system of analytical work, and that in spite of the earnestness of the individual chemist to arrive at truth for truth's sake alone, much diversity arises and leads to a great deal of confusion oftentimes. This is a feature that has always been observable in the labours of the most advanced masters in chemical science almost in an equal ratio as was to be found in the results of her most retiring students.

"Something has been gained certainly of late from the facility of intercourse which the railway, the steamboat, and the press have contributed, yet still it may be said that every chemist has his own codex and abides by it.

"Now I think the time has come for representative chemists and those advanced in collateral sciences to form a congress or convocation so as to produce such a digest of the various systems as would serve for a universal guide for analytical procedure and in accordance with which every result ascertained with honest care and attention, no matter where or by whom, would be comparable and of specific value.

"Lately a few persons chiefly occupying public official positions have given intimation of the need of such a convocation as I have alluded to. Far from me to question the laudableness of the union of these men in thought and action so as to secure conformity, yet I fear it must seem to a great many, as under some phases it does to myself, in the character of a species of trades union, and, inasmuch as it does so, inadequate to give that assurance of unbiassed truthfulness which I would wish to see."

The Secretary said that a committee had been appointed by the British Association to report on the analysis of phosphates and potash salts. He agreed with Mr. Murphy that more uniformity was desirable, but contended that considering that it was only within the last hundred years that analysis had been developed, we could hardly expect it to have reached perfection.

Mr. Murphy said that he thought that the production of a standard work on analysis would be the result of such a congress as he advocated. To such a work all would gladly contribute.

A vote of thanks to Mr. Murphy concluded the meeting.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The twenty-fourth annual meeting of this Society was held in Anderson's University, 204, George Street, Glasgow, on Wednesday evening, 14th April. Mr. John Currie, the retiring President, occupied the chair.

The preliminary business included the announcement of a donation from Mr. Duncanson, of Stirling; the report from the Early Closing Committee, by Mr. Murdoch; and the adoption of a motion proposed by Mr. J. A. Clarke, to the effect that the past presidents of the Association be distinguished on the printed syllabuses of the Association in some way from the other members.

Mr. McCann then moved: "That on and after the end of the session no member of the society shall be eligible to hold office unless he agrees to shut his place of business at 8 o'clock."

Mr. Murdoch moved the previous question, which was carried by a large majority, only six voting for the motion.

The Honorary Secretary (Mr. J. M. Fairlie) was then called upon, and read the Council's Annual Report. It touched on the operations of the Adulteration Act, pointing out that only two druggists (one a surgeon druggist) had been prosecuted under this Act, in Glasgow, namely, in the scammony cases, and as it was well known the inspector had made purchases from the bulk of the chemists in town, it showed that so far as the drug trade in Glasgow was concerned the Act had little effect. The report then referred to the great outcry that had been made regarding lead in soda-water, which to some extent was justifiable, yet the water used had a great deal to do with it, as the same complaints were not made where the water used was of a "harder" nature. As regards the "morning tonic" question, the less they as pharmacists had to do with medicines in this special form the better. Referring to the British Pharmaceutical Conference, it was suggested to send a deputation to Bristol in August next, to invite that body to Glasgow in 1876. Coming to the particular work of the Association, a small but excellent library had been established which, together with Mr. Price's manuscript prescription book, and the Messrs. Evans' materia medica cabinet and microscope, had been largely taken advantage of by the members; and in connection with the microscope, Mr. Hunter, President of the Assistants' Section, had mounted a large number of objects which had proved of great interest. Eight lectures had been delivered during the session, apart from the eight meetings of the Assistant Section, each had been reported regularly in the *Pharmaceutical Journal* and *Chemist and Druggist.* Two of the lectures, viz., that on "Zymotic Poison," by Dr. Dougall, and on "Some of the Laws of Health," by Dr. Miller, had been published in full by the courtesy of the editors of these journals, and two hundred and fifty copies of each had been distributed among the members and friends, and the Council desire a special vote of thanks to the proprietors for their kindness. Dr. Black, one of the lecturers, had left the city for London, and the Council wish him every success in his new sphere. The only lecture announced on the syllabus and not delivered was that on "Electrical and other Influences in the Atmosphere on the Death Rate," Dr. Slirton being engaged at the time on some government work, but it will be delivered next session. Mr. Emmerson MacIver, F.C.S., took his place, his subject being the "Spectroscope." For beautiful illustrations and striking mechanical effects, the lecture of the President of the North Branch of the Pharmaceutical Society (Mr. Gilmour) on "Chromatic Phenomena of Crystallization," and that on "Artificial Illumination," by Mr. Dittmar, of the Andersonian, were much admired.

Two classes had been organized at the commencement of the session; about forty members joined the tutorial class, conducted by Mr. Lindsay, B.Sc., and twenty enrolled for the practical chemistry class, conducted by Mr. Dittmar. The education committee has visited their classes from time to time and report very favourably regarding them. A botany class is now being organized to be under the superintendence of Mr. Keddie, Teacher of Science, Free Church College, which it is hoped will be largely taken advantage of.

The early closing movement is in much the same position as last year, some adhering to the 8 o'clock hour, others evading it. The trade price list committee have had several meetings, and a remit was made to the Association for larger powers. This was referred to a special meeting of the trade, held on the evening of 16th December last, but as there were few country members present, it was adjourned till the 13th of January, at mid-day. This meeting was a most successful one in point of numbers, while letters of apology were read from different parts of the country. The decision come to was that the price list committee should have power to enlarge the next edition of the list, and if thought advisable amalgamate it with that published in Edinburgh. The council also thought that the question of examinations and fees should be considered at these meetings, which was accordingly announced on the circular convening them. The result was that after deliberation a draft memorial was agreed to be presented to the London Council, which has been done; and judging from the reception it has received already, and the threat held out that instead of granting concessions, the Council is contemplating further restriction, another special meeting of the trade may, therefore, be necessary, to appoint a strong deputation to attend the annual meeting in May, so as to lay the whole matter before the Society at large.

The Council have to acknowledge that the Assistants' Section has been a great help to the Association this session, the whole of the committee working most harmoniously together, the services of the active Secretary, Mr. J. Foster, deserving special mention. The membership and subscriptions have very materially increased this session, and now stands at forty-five employers, sixty assistants, and twenty-one apprentices. It is hoped that the same energy and enthusiasm which has characterized the whole proceedings this session will go on from year to year so that all connected with the business may derive the benefit which ought to accrue from a large and powerful organization such as should exist in this great city of industry and capital.

The financial statement was then read by the Treasurer, Mr. McKenzie, of which the following is an abstract:—

RECEIPTS.

	£	s.	d.
To Library Fund	39	7	6
,, Class Fees	54	0	0
,, Festival Accounts	45	11	9
,, Donations and Subscriptions	23	14	6
,, Price List Sales	3	17	0
	£166	10	9

PAYMENTS.

	£	s.	d.
By Library Account	22	1	10½
,, Classes ,,	65	6	6
,, Festival ,,	45	0	0
,, Hall Rent, Printing Account, Postages, etc.	19	9	6
,, Balance of Cash	14	12	10½
	£166	10	9

The reports were unanimously adopted.

The Secretary of the Assistants' Section then read the report of their committee, which was remitted to the section for its approval at their business meeting on the 28th inst.

The election of officers, etc., for the ensuing year was then proceeded with, the following being the result:—President, Mr. William Greig (New Apothecaries' Company); Vice-President, Mr. Alexander Kininmont; Treasurer, Mr. J. McGill Murdoch; Hon. Secretary, Mr. J. M. Fairlie. Council: Messrs. John Currie (Sauchiehall Street), D. Frazer, T. Davison, J. Jaap, R. C. Rait (Partick), James McDonald (Glasgow Apothecaries' Company), W. Whyte, J. Fenwick, R. Brodie, J. A. Clarke, A. Paul, G. Garry, and W. McKenzie. Auditors: Messrs. J. C. Steele and James Whitelaw.

On the motion of Mr. Greig, seconded by Mr. J. A. Clarke, a vote of thanks was awarded the retiring officers, for which Mr. Currie responded. The meeting separated at a late hour.

HULL CHEMISTS' ASSOCIATION.

The winter course of lectures delivered by Mr. H. J. Parson, in connection with the Hull Chemists' Association, is just concluded, the number of students having been slightly in excess of last year. The lectures comprised Chemistry, Materia Medica, and Pharmacy, and these were followed by examinations in each subject. The prizes for the first two were offered by the Association, and Mr. G. Myers, Vice-President, gave one for Pharmacy. The results were as follows:—

Chemistry .... Mr. E. A. Allison.
Materia Medica .... Mr. W. G. Blythe.
,, ,, ... Mr. E. A. Allison.
Pharmacy...................... Mr. W. G. Blythe.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 15th April, 1875, Professor Abel, F.R.S., in the chair. The ordinary business of the Society having been transacted, Mr. J. W. Thomas read a paper "On the Gases Enclosed in Coals from the South Wales Basin, and the Gases Evolved by Blowers and by Boring into the Coal Itself." These gases were found to be marsh gas, carbonic anhydride, and nitrogen in all three of the classes of coal examined, namely, bituminous coals, steam coal, and anthracite. A paper "On Narcotine, Cotarnine, and Hydrocotarnine, Part I," by Mr. P. H. Beckett and Dr. C. R. A. Wright, was then read by the latter, after which Dr. H. E. Armstrong communicated a "Note on Isomeric Change in the Phenol Series." The meeting was finally adjourned until Thursday, 6th May, when the following papers will be read:—"The Quantitative Separation of Iron Sesquioxide, Alumina, and Phosphoric Acid," by Dr. W. Flight; "On Andrewsite and Chalkosiderite," by Professor N. Story Maskelyne; "On Sodium Ethylthiosulphate," by Mr. W. Ramsay; and "On a Milligrade Thermometric Scale," by Mr. J. Williams.

Parliamentary and Law Proceedings.

The Sale of Food and Drugs Bill.

The House of Commons went into Committee on this Bill on Tuesday last, the 20th inst. When the first five clauses had been considered and agreed to with amendments the Committee reported progress.

In the course of the discussion on clause 2,

Mr. W. Stanhope moved that "water" should be inserted after "drugs" to make it clear that water might, under this Bill, be subject to analysis.

On Clause 3,

Dr. Cameron moved the omission of the word "knowingly" in the fourth line, because if it were necessary in order to obtain a conviction to prove that a vendor of adulterated articles knew they were adulterated it would be impossible to obtain a conviction.

Mr. Sclater-Booth thought the hon. gentleman should have directed his observations to a subsequent part of the clause, and not to this, the first part of it. As the first part of the clause would impose a punishment of six months in case a person permitted articles injurious to health to be bought from him, it was only reasonable that a guilty knowledge should be proved against him before convicting him.

Dr. Playfair thought his hon. friend was right in asking for the first "knowingly" to be left out, but he would preserve the second "knowingly."

Sir A. Lusk said that the magistrates were always tender with a man who broke the law from ignorance, and he would keep the word "knowingly" where it was in the Bill.

Mr. Gordon was of opinion that the onus of proving his innocence should be thrown upon a tradesman who mixed one thing with another so as to be injurious to health.

Mr. Forsyth would retain the word "knowingly." The House did not wish to punish offences committed accidentally.

Mr. J. Fielden predicted that the Act would be quite inoperative if the word "knowingly" were retained.

Mr. W. E. Forster said that the accidental tradesman would be sufficiently protected by the clause, but that the word "knowingly" would enable a trader to escape conviction when he ought to be convicted.

Mr. C. P. Villiers thought the Committee ought to know that this Bill was regarded with great suspicion, because it weakened the security which the former Act was intended to give against the practices and usages of trade. The present Bill, however, went in the other direction, and all sorts of excuses would be made that the tradesman had procured the adulterated article from some one else. If the Committee were in earnest in putting down adulteration, they ought not to insert these unnecessary words.

Mr. Sclater-Booth thought that the right hon. gentleman could not have read the original Act. The clause exactly followed the language of the old law, except that it used the word "knowingly" instead of "wilfully."

Sir J. Kennaway said it was important the word "knowingly" should be taken out, because it gave a wrong impression in regard to the wish of the House. If the word were omitted it was by no means likely that an innocent man would be convicted.

Mr. Sullivan said that an Act of this kind in Dublin had been obstructed for several years by the insertion of this word "knowingly." The City analyst again and again brought the vendors of "sweetstuffs" before the magistrates, but they were always able to throw the onus back upon the manufacturers, and the children continued for some years to be poisoned until an alteration of the Act could be obtained. He warned the House that if the word "knowingly" were left in the clause it would obstruct the operation of the Act in the same way.

Mr. Mundella was of opinion that there was very little adulteration of food in the country. It would not pay as a rule to adulterate. He hoped the Committee would not make the Bill too stringent, as if they did magistrates would not convict.

Mr. Boord hoped that if the word "knowingly" were retained it would be explained and defined.

Dr. Playfair observed that the first "knowingly" was not required in the clause. If a person mixed deleterious materials with food, he must be taken to do so with the intent to adulterate.

Sir H. Peek concurred with the hon. member for Sheffield that there was not so great an amount of adulteration practised as some hon. members seemed to think, and that opinion was borne out by the report of the Select Committee.

The amendment was then agreed to.

Mr. Sullivan moved the insertion after the words "any article of food with any ingredient or material," of the words "whereby to reduce its value as an article of commerce." The effect would be to prevent the adulteration of food by substances which were not poisonous—such as of milk by water.

Mr. Sclater-Booth pointed out that the cases to which the hon. gentleman alluded were sufficiently provided for by Clause 3.

The amendment was withdrawn.

Dr. Cameron moved the omission of the word "knowingly" in the clause.

Mr. Forsyth said that it would be extremely hard upon shopkeepers if the word "knowingly" were omitted from the clause, because they would in that case be liable for any improper ingredient which might be introduced into an article which they received from the wholesale manufacturer abroad.

Mr. W. E. Forster thought that the word could not in justice be struck out.

Mr. Sclater-Booth believed that the word must be retained.

Mr. Macdonald should support the amendment of the hon. member for Glasgow.

Dr. Cameron, after what had fallen from the right hon. gentleman below him, would withdraw his amendment.

The amendment was withdrawn.

Sir A. Lusk proposed the insertion in lieu of the word "of," of the words "not exceeding," with a view of leaving it to the discretion of the magistrates whether a lesser penalty than £50 might not be inflicted.

The amendment was supported by Mr. Watkin Williams and others, and opposed by Mr. Denison, who did not think the penalty named in the clause too severe, seeing that the offence must be proved to have been knowingly committed. The amendment having been accepted by Mr. Sclater-Booth, was eventually agreed to.

Mr. O'Sullivan rose to propose an amendment, the object of which was to prevent the sale of a compound known as "silent" whisky. He had asked a friend of his to try the liquor without letting him know what sort it was. His friend drank it, and seeing he made a wry face, he asked him what he thought of it. His answer was, "It was like a torchlight procession going down my throat." By adulterating with rubbish which was bought at 2*s* 8*d*. a gallon, of course the genuine article, which was worth 6*s*. a gallon, could be under-sold. And the Government encouraged that practice, which was so injurious to the health and the sanity of the people. In the Government stores there were sometimes large quantities of so-called Dublin whisky, which contained only a very infinitesimal percentage of the genuine article, or even none at all. The Government gave the same permit for the sending out of that poisonous and deleterious stuff as for genuine whisky, and thus the purchaser and the consumer were deceived and defrauded. The only object of that could be to destroy a branch of Irish industry. That was no laughing matter. The Irish woollen trade had been destroyed by an Act of Parliament; but in the present case the same thing was being done by more subtle means—viz., by a fraud on the public. He declared he should persevere until the injustice of which he complained was removed.

Mr. Brooks said a real injury was done to an Irish industry, and he hoped his hon. friend would go to a division.

The Chancellor of the Exchequer said this matter lay a little outside the Bill. If the question was as to the mixing of any article that would be injurious to health that was already prohibited by the Bill, but if it was intended to take advantage of this clause to prevent the mixing of whisky in bond then it went far beyond the scope of the Bill. He suggested that the hon. member should make an appointment to see him and talk the matter over with him, the practical officers of the Customs being present, so as to come to a settlement.

Mr. O'Sullivan said the consumers got no information that the whisky was blended, as there was only the letter "B" rudely scratched on the casks. He would accept the offer of the right hon. gentleman, the Chancellor of the Exchequer.

Mr. Butt thought the matter was within the scope of the Bill, but advised his hon. friend to accept the right hon. gentleman's offer, on condition, however, that he should not be put to the test of tasting any of this whisky.

The amendment was then withdrawn, and the clause agreed to.

On Clause 4,

Dr. Cameron proposed to omit the words, "of a nature injurious to health" in the case of drugs, which might be adulterated to an extent very prejudicial to the health and even to the life of a patient, by means of substances which were not injurious to health. Besides, chemists were not likely to do anything ignorantly, and therefore there could be no hardship in compelling them to sell their drugs in a state of purity.

After some conversation, Dr. Cameron's amendment was withdrawn to give place to the following, which was adopted:—

"So as injuriously to affect the quality or potency of such drug."

Dr. Lyon Playfair moved the omission of the word "knowingly," on the ground that the persons who would be affected by this clause would not be ignorant shopkeepers, but chemists and druggists, who ought to be better informed as to the nature and quality of the articles they sold.

Mr. Mundella and Mr. Pease opposed the amendment.

Mr. Sclater-Booth said he had received representations from the Pharmaceutical Society, who could scarcely be supposed to desire the sale of adulterated drugs, against the principle of the amendment. He therefore hoped the proposal would not be pressed.

Dr. Playfair withdrew his amendment in deference to what appeared to be the will of the House, and not because he had changed his view.

The clause as amended was added to the Bill.

On Clause 5,

Lord F. Cavendish moved to amend the clause by inserting after the word "appearance" the words "unless such matter is used to conceal the inferior quality of the article."

The amendment was adopted.

Clause 5 was then agreed to, upon which the Chairman was ordered to report progress.

The following tabular arrangement will allow of a comparison of the five clauses of the Sale of Food and Drugs Bill that have thus passed through Committee with the corresponding portion of the Bill as originally introduced under the title of the Adulteration of Food and Drugs Bill:—

As read a first time; the parts now altered or omitted printed in italic:—	As agreed to by the Committee; the new and altered parts printed in italic:—
1. From the commencement of this Act the 23 and 24 Vict. c. 84, 31 and 32 Vict. c. 121, s. 24, and the 35 and 36 Vict. c. 74, shall be repealed, except in regard to any appointment made under them and not then determined, and in regard to any offence committed against them or any prosecution or other act commenced and not concluded or completed, and any payment of money then due in respect of any provision thereof.	1. From the commencement of this Act the *statutes of the* twenty-third and twenty-fourth of Victoria, chapter eighty-four, *of the thirty-first and thirty-second of Victoria, chapter one hundred and twenty-one, section twenty-four*, of the thirty-third and thirty-fourth of Victoria, chapter twenty-six, section three, and of the thirty-fifth and thirty-sixth of Victoria, chapter seventy-four, shall be repealed, except in regard to any appointment made under them and not then determined, and in regard to any offence committed against them or any prosecution or other act commenced and not concluded or completed, and any payment of money then due in respect of any provision thereof.
2. *This Act shall not apply to Scotland or Ireland except as herein provided.*	
3. The term "food" shall include every article *eaten or drunk by man other than drugs*:	2 [formerly 3]. The term "food" shall include every article *used for food or drink by man, other than drugs or water*:
The term "drug" shall include medicine for internal or external use:	The term "drug" shall include medicine for internal or external use:
The term "county" shall include every county, riding, and division, as well as every county of a city or town not being a borough:	The term "county" shall include every county, riding, and division, as well as every county of a city or town not being a borough:
The term "justices" shall include any police and stipendiary magistrate invested with the powers of a justice of the peace.	The term "justices" shall include any police and stipendiary magistrate invested with the powers of a justice of the peace *in England, and any divisional justices in Ireland.*

Description of Offences.	*Description of Offences.*
4. No person shall *knowingly* mix, colour, stain, or powder, or order any other person to mix, colour, stain, or powder, any article of food with any ingredient or material *of a nature* injurious to health, with intent that the same may be sold in that state, and no person shall knowingly sell any such article so mixed, coloured, stained, or powdered, under a penalty in each case *of* fifty pounds for the first offence; every *subsequent* offence, after a conviction in such penalty, shall be a misdemeanour, for which the person, on conviction, shall be imprisoned for a period not exceeding six months with hard labour.	3 [formerly 4]. No person shall mix, colour, stain, or powder, or order, *or permit* any other person to mix, colour, stain, or powder, any article of food with any ingredient or material *so as to render the article* injurious to health, with intent that the same may be sold in that state, and no person shall knowingly sell any such article so mixed, coloured, stained, or powdered, under a penalty in each case *not exceeding* fifty pounds for the first offence; every offence, after a conviction *for a first offence*, shall be a misdemeanour, for which the person, on conviction, shall be imprisoned for a period not exceeding six months with hard labour.
5. No person shall *knowingly*, except for the purpose of compounding as hereinafter described, mix, colour, stain, or powder, or order any other person to mix, colour, stain, or powder, any drug with any *other* ingredient or material *of a nature injurious to health*, with intent that the same may be sold in that state, and no person shall knowingly sell any such drug so mixed, coloured, stained, or powdered, under the same penalty as in the *last clause* for a first and subsequent offence.	4 [formerly 5]. No person shall, except for the purpose of compounding as hereinafter described, mix, colour, stain, or powder, or order *or permit* any other person to mix, colour, stain, or powder, any drug with any ingredient or material *so as to affect injuriously the quality or potency of such drug*, with intent that the same may be sold in that state, and no person shall knowingly sell any such drug so mixed, coloured, stained, or powdered, under the same penalty *in such case respectively* as in the *preceding section* for a first and subsequent offence.
6. No person shall *knowingly sell* any article of food or any drug which is not of the nature, substance, and quality of the article demanded by the purchaser, under a penalty of twenty pounds, except as herein excepted and provided; that is to say, except— *Where any matter is mixed therewith for the purpose of rendering it portable, or of preserving it;* *Where a harmless ingredient is mixed with it for the purpose of rendering it palatable or of improving its appearance;* *Where according to the usage of trade it is sold in a mixed state;* *Where it is the subject of a patent in force, and is supplied in the state required by the specification of the patent;* *Where British, colonial, or foreign spirits are reduced from their ordinary strength by persons licensed and paying duties under the excise;* *Where a drug is compounded either in conformity with a prescription of a registered medical practitioner or otherwise according to the usage of trade;* Where the article is unavoidably mixed with some extraneous matter.	5 [formerly 6]. No person shall *sell to the prejudice of the purchaser* any article of food or any drug which is not of the nature, substance, and quality of the article demanded by such purchaser, under a penalty of twenty pounds, except as herein excepted and provided; that is to say, except— *Where any harmless matter or ingredient is mixed therewith for the purpose of rendering it portable or palatable, or of preserving it, or of improving its appearance, unless such matter is used to conceal the inferior quality of the article.* *Where the article named is a proprietary medicine, or is the subject of a patent in force, and is supplied in the state required by the specification of the patent;* *Where a drug is compounded as hereinafter described;* Where the article is unavoidably mixed with some extraneous matter *in the process of collection or preparation.* *Provided that no article shall be deemed to be within any of the exceptions above set forth, if the matter or ingredient mixed therewith shall have been added with intent fraudulently to increase the bulk, weight, or measure of the article.*

Poisoning by Vermin Killer.

On Wednesday, April 14, Dr. Diplock held an inquest concerning the death of Clara Emma Banbury.

Thomas Saul Banbury, Box Villa, Albion Road, Hammersmith, gentleman, stated that deceased was his daughter; her age 29 last birthday. The deceased was single, and in her ordinary health on Monday, except that she had a delusion that her mother would die first. At twenty minutes past ten on Monday night she bought a tin of ox-tail soup at Walton, Hassell, and Port's, but her mother did not like it, and witness thought she must have purchased the poison with which she killed herself. The deceased was of a very affectionate disposition. On Tuesday morning witness thought he heard her go down at seven o'clock, but on getting up found her door open, and went in and saw deceased on the floor on a thick petticoat. Witness fetched Dr. Chapman, and found part of the poison in paper, and on looking round saw the glass, with some contents of a crystalline character.

Dr. C. W. Chapman stated that he was called to see the deceased on Tuesday morning at a quarter past eight o'clock. The last witness said his daughter was very ill or dying. Witness followed him, and found deceased dead; she had been dead some hours. On the dressing-table witness found a paper produced, with a pencil alongside, on which was written "My poor mother is dying of a broken heart, I will poison myself to-night. Oh, my poor father, and I hope I shall die.—April 10th.—Clara. I bought it at Walton, Hassell, and Port's. Oh, my poor father; Oh, God help me." Found also a packet of Battle's Lincoln Vermin Killer, marked "poison." Witness also found the glass it had been mixed in. Made a *post-mortem* examination and found the organs healthy, and took away the intestines for examination. The muscles of the face were drawn, and he believed in all probability she had died from strychnine poison.

One of the witnesses asked if such poison was allowed to be sold?

The Coroner said it was allowed to be sold as a compound. The evidence pointed to the cause of death. He had frequently called attention of juries to sleeplessness as the forerunner of suicide, and the necessity of persons being looked after when those symptoms appear.

The jury returned a verdict of "Suicide by poison while of unsound mind."

Several members of the jury complained of the readiness given to persons to purchase deadly poisons at these chandlers' shops that sold everything. They felt that the sale of poisons should be restricted to the law that affected chemists.

Dr. Chapman said that a packet of Battle's Vermin Killer cost threepence, and would kill five persons, or poisoning might be done at a half-penny per head. He concurred with the jury on the careless mode of sale. The most excruciating pain attended the taking of Battle's Vermin Killer.—*West London Observer.*

Poisoning by Caustic.

An inquest has been held at Brighton to investigate the circumstances attending the death of Alfred Richardson, aged 49 years, a commercial traveller.

William James, a hawker of publicans' beer cans, said that, at about half-past eleven at night, he was with deceased, whom he had known between five and six years, in the commercial room of the Prince Albert Hotel. Deceased, who was sober, asked him for some tobacco; and witness put his hand to his pocket and pulled out some in a piece of paper. In taking out the paper, he also pulled out a small pill box in which was a piece of caustic, about the size of an ordinary pill. The caustic fell on the table, and deceased picked it up. Witness went to light his pipe, when he heard deceased say "That's just what I wanted, an antibilious pill." Witness responded "Good God, you've not taken it?" and deceased replied "Yes, I have." Witness then exclaimed "You're poisoned, its caustic." Deceased replied "Well, if it is, I've got it," and then drank some ale, after which he said that he had a burning in his throat. Witness at once asked deceased to go to a doctor's, and they went to a chemist's in the street, and then to several surgeons, two of whom refused to get up. Ultimately they went to Mr. Hart, surgeon, who saw deceased. Witness and deceased returned home, and went to bed in the same room. At about three o'clock on Sunday morning deceased awoke and commenced murmuring, and witness got up and obtained some medicine from Mr. Hart. Deceased, however, got worse, and Mr. Hart was sent for; but deceased died about eight o'clock whilst witness had gone for some leeches. The box was marked "caustic—poison."

Mr. James Barker, assistant to Mr. Moon, chemist, Trafalgar Street, deposed to deceased having been taken to his employer's establishment on the night on question. Witness gave deceased some milk, some ipecacuanha wine and water, and an emetic, and afterwards accompanied him to Mr. Hart's. Whilst in the street, deceased remarked that it was all his own fault, he having taken the the caustic in mistake for a pill.

Mr. E. J. Hart, surgeon, deposed to attending to deceased, as mentioned. On seeing him on Sunday morning, witness found him exhibiting every symptom of suffocation. Witness went to the dispensary to get some instruments, and on his return performed tracheotomy and tried artificial respiration, but it was of no avail, and deceased died soon after. A *post-mortem* examination showed that the stomach and œsophagus were much congested, but beyond that there was no trace of nitric acid. Between the folds of the mucous membrane was a large red spot where the caustic had evidently lodged, and the passage to the lungs was completely blocked up by a swelling caused by the action of the acid. Thus the actual cause of death was suffocation.

The jury found that deceased met his death by misadventure. In drawing up the inquisition, the Deputy-Coroner highly commended Mr. Barker for the intelligence and care he had displayed and the trouble he had taken on the unfortunate man being brought to him.—*Brighton Herald.*

Review.

On British Wild Flowers Considered in Relation to Insects. By Sir John Lubbock, Bart., M.P., F.R.S. With numerous illustrations. London: Macmillan and Co. 1875.

The existence of sexual organs, even in flowering plants, has been generally admitted by botanists only in quite recent times. It was an Englishman, Nehemiah Grew, who first maintained, in his 'Anatomy of Plants,' published in 1682, the necessity for the action of pollen on the pistil for the production of fruit. The new doctrine was fiercely contested as heretical, and even impious, by some; by others, as Tournefort in 1700, on philosophical grounds. After Linnæus had firmly established the nature and functions of the reproductive organs, the next great step was made by J. G. Kölreuter, who published in 1761 his 'Vorläufige Nachricht von einigen das Geschlecht der Pflanzen betreffenden Versuchen und Beobachtungen,' wherein he maintained, as the result of his own observation, that in all Cucurbitaceæ, in all Irideæ, in the fig, and in not a few species of Malvaceæ, the pollination of the female flowers or organs is the work of insects alone; and that in Iris the relation of the various parts of the flower to one another is such that the pollen cannot reach the stigma either by itself or with the assistance only of the wind. He was also the first to notice the phenomenon of dichogamy, or the fact that in hermaphrodite flowers the male and female organs are very commonly not in a functional state at the same time. Kölreuter's work was followed, in 1793, by the better known and often quoted volume of K. C. Sprengel's 'Das neu entdeckte Geheimniss der Natur im Bau und in der Befruchtung der Blumen,' who supported his theorem that "Nature does not intend any hermaphrodite flower to be fertilized by its own pollen," by a great number of illustrations beautifully and ingeniously worked out. He also first called attention to the advantage enjoyed by bright-coloured and sweet-scented flowers in the inducements thus held out for the visits of insects. Kölreuter's and Sprengel's observations attracted, however, but little attention until within the last fifteen years, when—not to mention continental workers in the field—the writings of Darwin have directed a large amount of observation to the phenomena of the fertilization of flowers by the agency of insects.

In the little volume before us Sir John Lubbock gives a very carefully compiled and interesting account of the main facts brought out by older and more recent observers as far as British wild flowers are concerned. The introductory portion is devoted to the general subject which is explained in a manner to interest even the unscientific reader:—the part played by the honey in attracting insects; the advantage possessed by those individuals of a species which exceed the others in beauty of colour or scent, and the consequent probable perpetuation and gradual increase of their peculiarities; the inconspicuous character of "anemophilous" flowers, or those fertilized by the wind, as contrasted with the "entomophilous," or those fertilized by the agency of insects; and the mutual adaptation of the arrangement of the parts of the flower and of the structure of the legs and bodies of insects for the purpose of cross-fertilization. In the second chapter the special contrivances met with in natue are described, by which self-fertilisation is hindered or rendered impossible, and cross-fertilization promoted—dichogamy, dimorphism, etc.; and Sir John details a series of interesting observations tending to show that bees at least have a keen appreciation of differences in colour. In the remainder of the volume the author takes up each of the natural orders of flowering plants in succession, and gives a summary of the facts at present collected by diffeerent observers respecting the mode of fertilization of the various species belonging to it which are included in the British flora. As the author remarks at the close of the volume, the field is a very wide one, and our knowledge at present very limited; but the lover of nature could not wish for a better introduction to it than Sir John Lubbock's interesting little volume.

Notes and Queries.

[437]. CEMENT FOR COMPOSITION MORTARS.—A correspondent asks in last week's Journal for a form for a cement with which to repair composition mortars. He will find either of the three following effectual. I have used each in its turn, but give the preference to No. 2.

No. 1.—Take fresh slaked lime and mix it into a paste with the white of a fresh egg, having previously broken up the stringiness of the albumen by whisking it in a tea cup or jelly pot by means of a small bundle of fine iron wire.

No. 2.—Dissolve gum shellac in methylated spirits of wine or wood naphtha to the consistency of ordinary mucilage. Take of the finest plaster of Paris, such as is used by dentists for modelling, and mix with it so as to form a paste; apply speedily, as it soon sets. Time should be allowed for it to thoroughly harden, and the parts should be kept from shifting their position.

No. 3.—Take ordinary brick-dust, powdered fine. Mix this with mucilage of gum Arabic to the consistency of a stiff paste, and apply *sec. artem.* By ordinary brick-dust I mean the article used in most households for cleaning knives, and commonly known as Bath brick, but why so named I am at a loss to know, as the so-called Bath bricks are made of a peculiar sand obtained from the bed of the river Parret, near Bridgewater, in Somersetshire. This sand consists chiefly of the very minute skeletons of fossil infusorial animalcules, accumulated in beds of vast extent, and consisting of almost pure silica in a state of minute division.

P.S.—Nos. 1 and 3 have already been published, but I am not aware that No. 2 has, if so, I have never seen it; the idea occurred to me, and the cement has proved very satisfactory.—T. C. Maggs, *Yeovil.*

[438]. MICROSCOPIC EXAMINATION OF STARCHES. — How may specimens of various *starches* be best mounted for microscopic comparison? In glycerine or balsam I find the markings imperceptible. Is it possible by distinctive microscopic characters to discriminate between St. Vincent's or Natal arrowroot, and genuine "Bermuda," at five or six times the price?—Micro.

[439]. TOOTHACHE DROPS.—The following four recipes for "toothache drops," are quoted in the *American Journal of Pharmacy*, from the *Dental Cosmos* for November, 1874:—

1.—Chloroform,
Sydenham's Laudanum . . . āā ʒii
Tinct. Benzoin . . . . . . ʒi

2.—Creasot,
Chloroform . . . . āā ʒii
Sydenham's Laudanum . . . ʒiv
Tinct. Benzoin . . . . . . ʒi

3.—Oil of Peppermint,
Rhigalene,
Chloroform . . . . āā ʒiii
Camphor . . . . ʒii

4.—Chloral,
Camphor . . . . āā ʒi
Morphia . . . . gr. ii
Oil of Peppermint . . . . ʒii

Obituary.

Notice has been received of the death of the following:—

On the 3rd April, 1875, Mr. Henry J. S. Hopwood, Pharmaceutical Chemist, of Richmond, Surrey, aged 77. Mr. Hopwood was one of the Founders of the Pharmaceutical Society.

On the 11th April, 1875, Mr. Alfred Towerzey, Pharmaceutical Chemist, of Glasshouse Street, London, aged 66. Mr. Towerzey had been a member of the Pharmaceutical Society since 1842.

On the 20th March, 1875, Mr. James Bailey, Chemist and Druggist, of Oldham, aged 59.

On the 21st March, 1875, Mr. Sampson Rogers, Chemist and Druggist, of Shaldon, Devon, aged 35.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Glasgow Memorial.

Sir,—At a meeting of the Board of Examiners for Scotland held here this forenoon, attention was called to the "Explanatory Note" from Messrs. Currie and Fairlie, which appeared in last week's Journal in regard to a memorial sent to the London Council.

Without at present making any remarks on the extraordinary nature of the document thus sent for consideration to London, the Board distinctly states that the authors of the note already referred to are entirely in error when they say that circulars have been sent to several members of the Board convening meetings in connection with the draft memorial.

No such intimations were received by any of the members of the Board, with the exception of Mr. Kinninmont, of Glasgow, and the first notice of such a memorial was obtained from the printed copy appearing in the Journal of the 10th April.

Signed on behalf of the Examining Board,

William Tait, *Chairman.*

Edinburgh, 21*st April*, 1875.

Sir,—Referring to the proceedings which took place this forenoon, at the meeting of the Board of Examiners here, I think it right to state that I explained to the Board I had received from Glasgow a printed halfpenny post-card some time ago intimating a meeting of the West of Scotland Chemists and Druggists, but the terms of which I could not now recollect, having paid no attention to it. This is the only intimation of a meeting which I am aware of ever having received, and I certainly never for a moment construed it to mean an invitation.

Wm. Gilmour.

Edinburgh, April 21, 1875.

Sir,—The Glasgow memorial and explanatory note will doubtless receive due consideration at the next Council Meeting.

To preserve my own consistency, however, I beg to state that the parties who sign the note are in error when they say, "although Mr. Mackay has evidently forgotten it, circulars convening two or three public meetings, which were held to discuss the question, and at which the draft memorial was adopted, were sent to several of the Examining Board at Edinburgh, Mr. Mackay, if we mistake not, being amongst the number."

I am not an examiner, and the Board must speak for itself, but I distinctly affirm that neither directly nor indirectly was I aware of the proposed memorial, until I received the agenda of business to come before the last meeting of Council in London.

My regret is as deep as ever that our friends in Glasgow sent such a document as the one now lying on the Council Board in Bloomsbury Square.

John Mackay.

Edinburgh, April 20, 1875.

The Glasgow Memorial.—Further Explanations.

Sir,—To "hang a man and then try him" may be vastly agreeable to the operators, but it could not fail to be very much the reverse to the victim operated on. Such, as it seems to me, at least, is the case of the "Glasgow memorial" at present. As I am, in some measure, responsible, though all unwittingly, for this, I will, with your permission, add a few explanatory words to those already addressed to you on the subject by my neighbours and friends—Messrs. Currie and Fairlie.

First, the "memorial" was put into my hands for the first time during an animated discussion on the "Sale of Food and Drugs Act," and it was only by snatches when I could, while watching this debate in which I felt called on to take part, that I got it read at all.

When my friend Mr. Mackay got up, as he was permitted to do in consequence of his inability to be present at the meeting in May when the subject is, for the first time, to be formally discussed, he not only had in his hand, as it seemed to me to be, a verbatim copy of the report, but in the course of his speech he mentioned, as I heard it, that he had been in possession of it from the previous Saturday morning. I did not, and do not complain of this, but on the surface it proves in how superior a position he was for entering upon its discussion to myself, or, I suppose, any other member of Council present.

Notwithstanding this disadvantage, from having previously had a general knowledge of the points discussed in the memorial, and from three or four brief jottings of these points taken on reading the document itself at the table, I was quite willing, as I repeatedly stated to the Council, to discuss it on its merits at once, and to give it a general support, had I only had pointed out to me by any of my more experienced colleagues the proper form in which to do it.

No one coming to my rescue in the matter, I declined absolutely, as I still do, to enter upon the merits till I could do so in proper form, stating as my reason for this course, I had no idea of allowing the question "to end in mere talk," as I never cared "to bark when not prepared to bite."

Second, as to the large amount of argument founded by yourself and others upon the numbers present at the last meeting of the Glasgow Council, when the memorial was finally adopted. If you will kindly ask our admirable reporter to look over his notes, you will probably find that when Mr. Mackay founded an argument against the memorial on the smallness of the meeting at which it had been adopted in my presence, I interrupted him in his statement, and explained that the matter had been discussed over and over again during the previous six months, but, that not having been present at their previous meetings, I could not state how many members were present at them. Mr. Mackay, then, you will also find, or should find, spoke of this as a great aggravation of the offence. He complained of the little confidence placed in the Edinburgh Board or Council by the Glasgow memorialists as proved by their meetings not having been reported to their friends in Edinburgh.

Third, as to your deeming yourself called upon to discuss the whole question in your leading article, and as to your permitting it to be discussed in your correspondence columns. Technically, doubtless, from the memorial itself having appeared in your columns, you were quite entitled to do this. But I consider that in the circumstances of its discussion being delayed till May, the publication of the memorial was a distinct mistake. Hence my great surprise at seeing it published at full length in our Journal.

In conclusion, I hope you will excuse my adding that I think it was hardly generous to me, and that I feel pretty sure it was not wise, either on the part of any member of Council, or on your own part, to enter upon a discussion of the memorial on its merits till I had an opportunity of bringing it in proper form before the Council. I greatly regret the trouble and loss of time I have caused to the Council and to yourself from my ignorance of the form in which to treat such a document as the "Glasgow Memorial."

DANIEL FRAZER.

Sir,—It is most unfortunate that the memorial from Glasgow should have been so worded as to convey to all outside the circle of its immediate authors an impression that it is an attack on the constitution and character of the Boards of Examiners, especially in Scotland.

However much its words seem to bear out this interpretation, I am certain that no such insult was intended, and confidently affirm that at no meeting of the trade in the West of Scotland, whether of sixty or of nine members, would such a document have been adopted, had the import of its phrases been carefully considered; indeed some of the members of the Glasgow council who were present at the meeting at which the memorial was finally adopted, have stated to me that they supported it only after Mr. Fairlie's assurance "that as to the changes suggested, their Edinburgh brethren were one with them," and so the objectionable phrases passed unobserved.

I regret much that business engagements prevented me from being present at the second meeting, and the final one was called on a day on which I was acting as examiner in Edinburgh, so that I had not an opportunity of seeing the memorial before its appearance in the Journal.

Had I seen it, I think I should have observed the absurd position we seem to assume in it, namely, that of censuring, as members of the council of the Glasgow Druggists' Association our own conduct as members of the Council of the North British Branch in the mode of nominating examiners, etc.; and as four of our members possess this double qualification, we are made to appear ridiculous in complaining of certain things being done, of which the blame, if blame there be, falls on ourselves.

As to the mode of appointing examiners, it is impossible to conceive of any system more liberal than that at present in operation. As stated in the letter of "Scotus," a Council is elected by balloting papers, one of which is sent to every member of the Society in Scotland. This Council is now composed of members resident in Edinburgh, eight; Glasgow, four; Dunfermline, one; Stirling, one; Portobello, one; so that of the fifteen we have a fair share of representatives.

Any member of the Council can nominate such persons as they think fit for the post of examiner, guaranteeing, of course, that their nominees will serve if elected. We have never had any need to have recourse to a ballot, as the difficulty has been to make up the number, and Mr. Mackay and others of the Board have frequently endeavoured to induce members from different parts of the country to allow themselves to be nominated—without success. I have also tried hard to get another from Glasgow, but "they all, with one consent, make excuse."

In conclusion, I hope that my Edinburgh brethren will accept of this explanation as to the apparently insulting expressions in the memorial, and that the London Council, setting aside all idea as to resenting the supposed attack, will proceed calmly to discuss the other points suggested in it on their own merits.

ALEX. KINNINMONT.

Sir,—In all the vague and disagreeable insinuations of the Glasgow memorialists, it is satisfactory to have at least one positive assurance even though it has been obtained by the help of an explanatory note, viz.: that it was not intended in any way to impugn the honour of the Board of Examiners in Scotland, past or present, or in any way cast the slightest reflection upon them. This is so far satisfactory. But it would have been more satisfactory still had we also obtained the assurance of what they did mean by asserting that the present system of examination was inimical to the future progress of the trade and estranging young men from the business, and what was further meant by tacking on to this assertion the demand that the Board should be drawn from a wider area, that there should be a change in its constitution yearly, and (singularly modest request) that it should sit twice a year in Glasgow. If the first part of the memorial is simply a philippic against examinations in general, nothing need be said against it here further than that it was unfortunate its meaning was not more clearly expressed. If, on the contrary, it means to insinuate something in the conduct of the examinations in Edinburgh different from that pursued in London; then the insinuations are entirely gratuitous and unwarrantable, inasmuch as the memorialists can have no direct knowledge of the understanding at present existing betwixt the two Boards other than the repeated assurance that at no previous time had they worked more harmoniously together, nor had the examinations more closely assimilated. It is almost inconceivable that the Glasgow druggists in the face of these assurances would still assume that there was a difference in the two examinations, and on the assumption draw out a public memorial, knowing it would be rigidly overhauled and criticized, both in the Council and out of it. What, then, can be the meaning and intention of this memorial?

In trying to solve this problem one is naturally led to consider the demand tacked on to the first part of the memorial for a general reconstitution of the Examining Board in Scotland; a most extraordinary demand, if we consider they impute nothing against the honour—and in the honour we assume the ability—of the present Board, nor against the mutual understanding existing betwixt the two Boards. Why should these demands have been tacked on to the allegations regarding the examinations, and above all, why should the examinations be associated (not certainly directly in as many words, but implied in every sentence of the memorial, and directly connected in Mr. Frazer's remarks) with the scarcity of assistants? It is here the cloven foot appears. That the Glasgow druggists are exercised regarding a scarcity of assistants is apparent, and that this scarcity is associated in their minds with the examinations may safely be taken for granted, and this being the case, what more natural than that they should seek to have these examinations changed; and how can they more effectually change them than by getting a Board appointed who shall give effect to their views? and how can they get such a Board appointed but by the means indicated in their memorial? Read in the light of this explanation, the whole memorial becomes clear as daylight; without it, it is the most unintelligible production that probably ever emanated from a public meeting. Be all this as it may, the subject of the appointment of examiners is of too great importance not to be seriously considered from every point of view, and in what remains of this letter I purpose considering the whole method of appointing examiners in Scotland without prejudice, so far as I know my own mind, either in favour of the present system or against the modifications suggested in the Glasgow memorial.

In considering then the whole question, there is at least one peculiarity connected with the Board in Scotland which tends to change, in some little degree, the relationship of that Board, in comparison with the London Board, to the Council, which must not be overlooked. This peculiarity is, that whereas the latter Board, as at present constituted (or even as probably it will ever be constituted), is in an eminent degree composed of men whose abilities and character are individually known, or may be known, to each member of the Council personally. This is not, and cannot be the case with the Scotch Board. Here, the members of the pharmaceutical body generally are comparative strangers to the Council. They are, with few exceptions, essentially unknown to them, either as regards ability or indeed any other acquirement specially fitting them for the important duties of examiners. The consequence of this is that to speak of a ballot under such circumstances becomes a mere farce if we would still retain the fittest men as examiners, unless there also accompany this ballot a nomination by responsible parties. Hence the wisdom of the Council—a wisdom I have always admired—of granting and giving effect to a Scotch nomination. But here the important question comes in, how and by whom should this nomination be conducted? In reply to this I answer, not assuredly by any individual or even body of individuals influenced by local opinions, local prejudices, and above all local jealousies. The Glasgow memorial itself, emanating though it does from a body say of sixty or seventy individuals (how many of these were assistants and apprentices?), is a stronger protest against local, which in other words just means indiscriminate, nominations than any argument which I could possibly adduce. No one can fail to see in that memorial the expression of local feeling alone, a feeling probably embracing in it both much of prejudice and jealousy, a feeling most certainly embracing in it the desire for a reduction of the examinations standard, elements I need not say, which if allowed at all to enter, would prove disastrous to the efficiency of the Scotch Board, and the harmony of both. If not then by individual, or even local action, we are of necessity shut up to a nomination by a representative body popularly elected so as to embrace not only all the localities, but all the opinions, and such a body I believe already exists in the executive which has hitherto nominated the examiners for Scotland. No system of election than that which this executive body has adopted, can be more representative or popular, none can work with greater simplicity, and none probably can call forth and embrace more diversity of feeling and opinion; so that after dispassionate consideration, I am more than ever persuaded that a nomination of examiners proceeding from such an executive is on the one hand the only safeguard against inefficiency and corruption, whilst it is calculated, on the other, to secure the election of the fittest.

But not only is there this question of ignorance of the acquirements and capabilities, on the part of the Council, of the individual members comprising the Scotch Board, but there are other points to be considered not less vital, which would make any interference by the Council such as indicated by the Glasgow memorialists dangerous in the extreme. Pre eminently there is this to be remembered, that as the establishment at present exists, and as it has hitherto existed in Scotland, connected with the examinations, there is an amount of detail work—not examinations, and yet belonging to the examinations—which must ever necessitate the great majority of the Board being drawn from the centre in which the examinations are held. This we believe will hold good to a certain extent even with the London Board, but much more is it applicable to the Board here destitute of an equipped establishment of appliances, not to speak of officials, such as there is at command in Bloomsbury Square. On this detail work, as everyone conversant with examinations well knows, depends much of the efficiency and success of the examinations, and to speak of a Board composed of members drafted from all parts of the country is simply absurd if this work is not to be slurred or left altogether undone and the very purposes of the examinations imperilled. Probably, however, the greatest absurdity of all is in the very supposition that a Board could be so constituted in Scotland—that is, with its members drafted in from all parts of the country. Only those who, like the executive here, have tried and found how limited are the sources from which men of known ability, with the inclination and time at their disposal to devote themselves to the irksome and thankless task of examinations, can know how absurd much of the Glasgow memorial truly is. Peculiarly absurd if the Board is to be completely revolutionized as to its members every two or three years; and to all their other hardships to have added the crowning absurdity of travelling throughout the country—we presume carrying their appliances with them like an itinerating mountebank, going to the assistants because the niggardly pittance received by them from their masters will not permit them to go to the examiners.

There are one or two other points which I would have liked to have taken up, but I have already, I am afraid, exceeded the limits allowable. I will, therefore, in the meantime, close with the intention of taking up the subject of the scarcity of assistants in another letter.

SCOTUS.

Sir,—With all due reverence for the wisdom of the Glasgow memorialists I cannot help holding that the alleged scarcity of assistants is almost wholly caused by the conduct of the masters, and that the Board of Examiners has got little to do with it, properly speaking. I should say that the scarcity is owing to the fact that assistants are underpaid and overwrought. The chief encouragement to most men to enter any business is the pecuniary one, and in this respect an assistant's inducement is infinitesimally small. Our trade is not keeping step with others in the march towards shortening of the hours of toil, and increase of remuneration.

It is really a psychological study to watch how thoroughly self-interest and the wished-for obesity of the money-bag can cause a body of presumably intelligent men to blink so hard at the real facts. I would suggest to some statistically inclined western druggist to devote a little of that time, previously given to the somewhat fossilizing occupation of memorial writing, to ascertain what the average wage of an assistant is, and I am much mistaken if his labour does not throw some light upon this dearth. The fact is that unskilled labour is often better paid.

Another most potent reason, especially in Glasgow, why men are unwilling to enter our ranks, or are keenly glad to quit them after having entered, is the monopoly which medical men make of the business, and the infinite number of "doctors' shops." The greatest hardship that a Glasgow druggist has to fight with is the fact that so many medical men make up their own prescriptions in shops palpably belonging to themselves; or worse still, under the bribe of a percentage upon their patronage they endeavour by every method piously to carry their prescriptions to the shrine of some particular druggist whose drugs are declared to be in a state of startling purity and newness, whilst hints are deftly given that all others are spurious.

This is a system which is a blot upon the medical profession, pharmacy, and on the independence of every honest man—a system which owl-like blinks at free-trade—a system also which causes many high-spirited young men to loathe the business and to quit it as soon as possible.

In conclusion, I hope that something may be done to stop the increasing number of "doctors' shops," and their degrading patronage of the druggist, that the masters will honestly endeavour to shut their shops at a human hour, and cease canting about their willingness to do so; that they will also share more justly and equitably their profits with those who help to make them; and then I may safely predict—without laying claim to be an oracle—that good men will easily be found.

PH. C.

Glasgow.

*** In reference to this subject Mr. James M. Fairlie also writes to say that if "*Scotus*" would send his name to him he might be induced to reply to the one point which "*Scotus*" embodies in so many queries, but that he shall treat all such anonymous communications with the silent contempt they deserve.

Mr. James McCann thinks the true explanation of the scarcity of assistants in Glasgow is to be found in the fact that the salaries offered to them after a four or five years' apprenticeship are only £45 for the first year, £50 for the second, £55 for the third, and £60 for the further term of their natural or unnatural lives, unless they are fortunate enough, after twelve years' experience, to reach the enviable position of first-at-the-counter, when they will be able to draw the sum of £80 yearly; and during all their time they will be expected to work about 90 hours per week. The average salary is estimated by Mr. McCann to be about half that received by a tailor, carpenter, bottle maker, painter, or even a sanitary or poor-law assistant inspector.

The Irish Pharmacy Question.

Sir,—I have read with interest the draft Bill proposed by the Chemists and Druggists' Society of Ireland for the regulation of pharmacy, etc., in this country, and would wish through your columns to call the attention of English pharmacists to one or two strange facts regarding the Council of the proposed Pharmaceutical Society of Ireland, as named therein.

In the first place, among the twenty-four names there is not the name of any one person who is actually at present engaged in pharmacy. The apothecaries who conduct the large medical establishments (some of which are inferior to none in the three kingdoms) in Dublin, Belfast, Cork, Limerick, etc., and whose interests would be seriously affected by the proposed changes, have been altogether ignored. It certainly seems a very strange proceeding indeed to appoint persons to make rules to regulate pharmacy and carefully exclude those who best understand the matter and are practically engaged therein.

Again, whoever framed the list seems to have forgotten that there were two such towns in this country as Belfast and Derry. Why the druggists of these towns (the most flourishing in the country) should be overlooked is to me an enigma.

The first six gentlemen on the list are medical men; of these the last two are apothecaries practising medicine, the representatives of the Apothecaries' Hall, and the most active members of that body in preventing the separation of medical practice from pharmacy in this country by the simple method of allowing the Irish apothecary of the future to be examined in matters merely relating to pharmaceutical science, as urged on the Directors of the Hall by a large number of the apothecaries themselves.

The other gentlemen, with the exception of Mr. Tichborne, are C. and D.'s (chemists and druggists, I presume, so called), and as there is no provision in the proposed Bill for their registration as pharmaceutical chemists, they would have to pass an examination before or possibly be rejected by examiners appointed by themselves. Perhaps they might examine and gives certificates to each other. They may be very estimable gentlemen, but, surely it would be well before appointing them, that something should be known of their attainments, beyond the fact that they keep open shop for the sale of drugs, patent medicines, colza and other oils, lamps, etc., etc., and call themselves chemists and druggists; perhaps the former on the *lucus a non lucendo* principle.

As I do not believe in anonymous letters I beg to sign myself,

HENRY WHITAKER,
Lic. Apothecary.

Japanese Peppermint Oil.

Sir,—In the Journal for April 17, there appears (as part of the proceedings of the North British Branch of the Pharmaceutical Society) a paper on "Solid and Liquid Japanese Oil of Peppermint," by John Mackay. The subject being one in which I have taken some interest, and Mr. Mackay acknowledging his indebtedness to a note by myself which appeared in the Journal for November 7, 1874, I would ask your permission to draw attention to one or two points which Mr. Mackay, in transcribing, has represented somewhat erroneously, possibly through a want of perspicuity on my part.

1. Mr. Mackay says, "Dr. Attfield refers to peppermint camphor under the name of menthene, believing it to be the hydrocarbon found more or less in all varieties of peppermint oil," and again "the result of his (Dumas') examination corresponded with that of Oppenheim and Attfield." In the first place, Dr. Attfield does not "refer to peppermint camphor under the name of menthene, believing it to be," etc., and in the second, Dr. Attfield (no disparagement to him) has never worked upon or examined peppermint camphor. In my note the first passage of the two given above runs thus: "Oppenheim called the subject of his experiments *camphor* or *stearopten of peppermint oil*, and also *menthol*. In Dr. Attfield's 'Manual,' peppermint camphor is styled, more systematically, I think, hydrous menthene,—menthene ($C_{10}H_{18}$) being the hydrocarbon which is known to be common to several, if not all, varieties of peppermint oil." What Dr. Attfield does is simply to choose from half a dozen names which are given to this body indiscriminately, the one which seems to him best to describe its constitution. I am glad to follow so good an authority in this. The last statement in the extract is my own, being added as merely explanatory of the systematic name.

2. Mr. Mackay says "menthol, a solid Chinese oil of peppermint, resembles in all its properties the solid portion of Japanese oil," thus restricting the name menthol to one particular solid, whereas it is a general term applied to the characteristic body of all oils of mint, whatever its physical condition or from whatever source.

3. Mr. Mackay says, "Nor can it be doubted that chemically, this menthol closely resembles, nay, is in all respects the same as the peppermint camphor obtained from our own or American oil [The latter differs from it considerably in physical properties.—J. M.], and that in fact both may be named a monatomic alcohol; menthylic alcohol, or hydrate of menthyl, being as already stated represented by $C_{10}H_{18} + H_2O$." The formula given is the constitutional one for hydrous menthene; menthylic alcohol or hydrate of menthyl would not be correctly represented by it, but by $C_{10}H_{19}HO$.

The amount of error in the statements above adverted to may seem trifling and scarcely worthy the notice here bestowed upon it; this notice may, however, prevent much misconception in the future. Further, it would not be conducive to that sound instruction, for the success of which Mr. Mackay, in common with all true pharmacists, is so much concerned, for statements not in accord with historical or scientific teaching to remain supported by his name.

To conclude, Mr. Mackay seems to give me the undeserved credit of having presented the specimens of solid and liquid oil to our museum. The crystallized oil was presented by Messrs. Cyriax and Farries: the liquid oil, quite independently, by another firm.

JOHN MOSS.

300, *Holborn.*

The Resin of Aloes.

Sir,—Your columns last week contained a long and elaborate paper on Aloes, by Dr. Craig of Edinburgh. As my name appears several times in the course of that communication, I must ask to be allowed to say at once that Dr. Craig gives me credit for statements about the activity of resin of aloes, which he may be right in characterizing as very absurd, but for which I cannot hold myself responsible.

Had Dr. Craig taken the trouble to ascertain correctly what my statements in connection with this question have been, he would have found that I have never expressed any opinion whatever regarding the physiological action of that substance.

The only expression of opinion to which I have ever committed myself definitely, is to be found in the proceedings of the Pharmaceutical Conference for 1870, and runs as follows :—

"Until new facts suggest a different conclusion, I hold that the soluble, brown, uncrystallizable substance which constitutes a considerable proportion of all aloes, is the part to which the purgative power is due."

The substance referred to here, was formerly called aloetin or aloesin and is none other than the changed aloin of Dr. Craig. So that the direct evidence, which was wanting, of the correctness of this view is now opportunely supplied by the experiments of Dr. Craig himself.

WILLIAM A. TILDEN.

Shanklin, Isle of Wight,

THE PHARMACOPŒIA DOSES.

Sir,—Mr. Cope's communication on the discrepancy of doses indicated in the Pharmacopœia for drugs and their preparations opens an important inquiry; but I do not think that he always appreciates correctly the cause of the apparent inconsistency. It does not follow that the pharmaceutical preparations of any given drug shall "contain its medicinal properties in an equally active condition," and therefore it does not follow that the doses should be susceptible of calculation by the rule of three. I have been more inclined to invert the reasoning adopted by Mr. Cope; and assuming the accepted dose to be the test of the efficacy of the preparation, it has appeared to me that the therapeutical value of the various processes might be to some extent measured by the relation between the dose and the percentage of the original drug.

To take an example from Mr. Cope's list: The product of extract from a given quantity of rhubarb may be as one to three; but the medicinal activity of extract of rhubarb prepared by the Pharmacopœia process is not greatly in excess of that of the powder, and it seems, therefore, inexpedient to perpetuate the formula. I may mention on the authority of the late Henry Deane, that when carefully prepared *in vacuo* the activity of extract of rhubarb corresponds very nearly with its percentage product. Syrup senna is an example of a wide range of dose (1 to 4 fluid drachms), and there is a corresponding uncertainty in the preparation as commonly met with. It is quite possible to prepare syrup senna in the Pharmacopœial proportions, but varying the *modus operandi*, which shall represent the active properties of the full quantity of senna employed. I doubt the possibility of doing this by the Pharmacopœial process, and it is not uncommon to find this useful domestic medicine almost inert.

The doses of the preparations of Peruvian bark are suggestive when regarded from the point of view proposed above. Besides the tincture (which, like all other tinctures except those of opium, belladonna, nux vomica, and a few other potential drugs it is better to exclude from the comparison of doses) there are three Pharmacopœial preparations of cinchona to which the following doses are attached, the dose of the powder being stated as 10-60 grains, viz. :—

Decoction Cinchona	. 1-2 fl. oz.	corresponding to Cinch. Bark	27-54
*Infusion ,,	. 1-2 ,,		22-44
Fluid Ext. ,,	. 10♏-30♏		50-150

If the foregoing table of doses is founded, as I believe it to be, on trustworthy observation and experience, modern pharmacy has little to boast of in connection with cinchona. The doses point to the old-fashioned decoction and infusion (the first changed for the worse by being strained cold, and both seldom used), as the most efficient preparations of cinchona. But they are bulky and inconvenient and practically the only pharmaceutical preparation which we can offer to the medical profession as a compendium of the virtues of the bark is the fluid extract, which medical experience estimates at one-third the value of the bark employed in its preparation!

Fluid extract of cinchona, when carefully prepared, may be made so as to produce an indifferent imitation of the cold infusion from which it is originally derived. It lays no claim to more than this, and how far it usually falls short, let those say who buy the article commonly offered and have observed how unlike the turbid mixture of fluid extract and water is to a freshly made cold infusion of cinchona.

Dr. De Vrij was right when he startled the last Conference with the vigorous declaration that "there is at the present time no good pharmaceutical preparation of cinchona," but his suggestion of an alcoholic extract scarcely appeared to be a satisfactory way of getting rid of the reproach.

RICHARD W. GILES.

* NOTE.—The decoction being ordered to be made up to measure while the infusion is not, the bark standard of these two preparations approximates so nearly, that the dose may be considered practically the same. The bark standard for fluid extract is taken higher than the Pharmacopœial formula which most operators would consider to be underestimated.

H. A. Millen.—Apply to the Secretary for a copy of the pamphlet entitled 'Hints to Apprentices.'

Election of Council.—We have received a letter from Mr. W. B. Clark, of Leicester, in which he states that it was with great surprise that he learned he had been nominated for the Council of the Pharmaceutical Society, and that it only was out of regard for the pressing requests of his friends that he allowed his name to remain upon the list.

"*Spero.*"—The treatment to be applied for the purpose you mention would depend on the nature of the substance operated upon. No general rule can be laid down.

"*Alpha.*"—There does not appear to be anything in the Pharmacy Act to prevent the use of the words in question, subject to the limitation of that Act.

H. E. G.—A formula for peppermint cordial will be found in vol. i. of the present series of this Journal, p. 497, or in any good book of recipes.

"*Excelsior.*"—Attending the lectures would not disqualify for the Bell Scholarship, but the passing of the Minor examination would cause your name to be removed from the list of Registered Apprentices and Students of the Society, who alone are eligible.

"*Curio.*"—You will find the information you require in the 16th section of the Pharmacy Act, 1864.

C. G. Rideal.—No.

H. W. J.—(1) Apply at Stationers' Hall. (2) Probably the deposit is due to the formation of a basic citrate.

"*Salicin.*"—You will find the information respecting salicylic acid in the *Pharmaceutical Journal* for November 28 last, p. 421.

J. Day.—Several formulæ for coloured solutions for window carboys have already appeared in the present series of this Journal.

"*Alpha.*"—Candidates for the office of dispenser in Her Majesty's Naval Hospitals must make a written application to the Director-General of the Medical Department of the Navy. See *Pharmaceutical Journal*, November 9, 1872, p. 364, or the Calendar of the Pharmaceutical Society.

"*Migrator.*"—The information has been asked for more than once in the Notes and Queries column, without, however, eliciting any reply. See Mr. Hustwick's "Australian Jottings," on p. 161 of the present volume.

J. W. Short.—(1) We believe not. Dr. Scoresby-Jackson's Note-Book of Materia Medica, published by Maclachan and Stewart, of Edinburgh. (2) Write to one of the Professors at 17, Bloomsbury Square.

We have received reports of meetings of the Manchester Chemists' Association, the Wolverhampton Chemists and Druggists' Association, and the Sheffield Pharmaceutical and Chemical Association, from the respective Secretaries, but are compelled to postpone their publication until next week.

COMMUNICATIONS, LETTERS, ETC., have been received from Mr. Barnes, Mr. Pocklington, Mr. Bennett, Mr. W. Robson, jun., Mr. Lomas, Dr. Spencer, Mr. Thresh, Mr. Alison, Mr. Ekins, Mr. Harvey, Mr. Short, Mr. Lewis. H. E. G., A. A., W. W., Q. E. D., H. W. J., Muricidaue, Alpha.

THE ALKALOID AND ACTIVE PRINCIPLE OF JABORANDI.

BY A. W. GERRARD,

Teacher of Pharmacy to University College Hospital.

Having, at the instigation of Dr. Ringer, performed a considerable amount of pharmaceutical work upon jaborandi, I was enabled to make some observations which I considered of value in undertaking a search for the principle to which this plant owes its useful and peculiar activity.

During the early part of Dr. Ringer's therapeutic investigations the bark of the stem was found upon administration to give results equal to that of the leaf; to the bark therefore I directed my attention in seeking for the active constituent. My reason for chosing the bark in preference to the leaf was principally the fact of its containing but a very small proportion of chlorophyll, which in the leaf is very abundant and troublesome to get rid of; experiments I had previously made upon the leaf partly failed on account of its presence, but this obstacle I have since overcome.

One thousand grains of bark, exhausted with 84 per cent. alcohol and the tincture evaporated, yielded 54 grains of soft extract, having primarily an astringent and bitter taste, in a few minutes developing upon the tongue a peculiar feeling of numbness and pungent heat of a persistent character. Two and a half grains were administered and produced the usual diaphoretic and sialogogue effects. The remainder of the extract was set aside till next day, when I found it had separated into two portions, one of a pale brown colour and bitter nauseous astringent taste, the other of a heavy green colour somewhat aromatic and very pungent to the palate. The pale coloured portion I found to be soluble, and the dark portion insoluble in water. To the bulk of the extract distilled water was now added, and the whole was well stirred with a glass rod. It was then thrown upon a filter, and the contents of the filter washed. The green colouring matter and acrid resin remained upon the filter. The filtrate was of a clear reddish brown colour and slightly bitter astringent taste. Two grains of the acrid green resin were administered without any result, and the dose was increased to four grains without effect. Recourse was then had to the filtrate, a dose proportionate to one drachm of the bark being administered. In fifteen minutes the full effects of the drug were produced. This result was therefore conclusive that the active principle was soluble in water, and had to be sought for in the watery portion of my substance. To three small portions of the solution I now added the usual alkaloidal reagents, viz., phosphomolybdic acid, phosphomolybdate of soda, iodohydrargyrate of potassium, and ammonia, all of which gave precipitates, the ammoniacal one being soluble in excess. The remaining solution was now evaporated to a small bulk, and after ammonia had been added in slight excess, divided into three portions. One was treated and shaken with chloroform, another with ether, the remaining one with benzol. All three of them emulsified more or less, and were set aside twenty-four hours to separate. The chloroform, upon removal and evaporation, yielded a small portion of soft pale coloured residue, having a slight bitter taste and faint aromatic odour. Half a grain was administered and gave the full effects of the drug. The ether solution treated in the foregoing manner yielded less, but it had a more aromatic fruity odour; half a grain was administered with the desired result. The benzol solution yielded a small quantity of substance similar to the others, but not in sufficient quantity for administration.

The portion of the active principle which remained was only sufficient for a verification of its alkaloid reactions. I have, however, more of it now ready, upon which I intend working chemically. From the preceding it may therefore be concluded that the resultant principle I obtained was an alkaloid which, at Mr. Holmes's suggestion, I will call pilocarpine. Whether it can be obtained in a crystalline form is matter for further experiments; but judging from its soft character, this is somewhat doubtful.

As a digest of the means I have previously described for its preparation and a consideration of its properties I find it may be easily obtained by the following process:—

Prepare a soft extract either of leaf or bark with 50 per cent. alcohol. Digest this with water, filter and wash. Evaporate the filtrate to a soft extract, cautiously add ammonia in slight excess, shake well with chloroform, separate the chloroform solution and allow it to evaporate; the residue is the alkaloid pilocarpine with probably a small amount of impurity.

Besides the alkaloid, jaborandi contains an acrid resin before mentioned, tannic acid, volatile oil, and chlorophyll. The acrid resin is soluble in ether, and possesses properties which indicate it to be the substance by which the effects of its external application are produced. All of the doses given were administered under the direction and supervision of Dr. Ringer.

THE ANTISEPTIC ACTION OF SALICYLIC ACID.*

BY DR. RICHARD GODEFFROY.

Salicylic or spiroylic acid, is an acid of the group of so-called aromatic componds, and is represented by the formula $C_6H_4 \left\{ \begin{matrix} OH \\ COOH. \end{matrix} \right.$ It occurs in the leaves of *Spiræa Ulmaria* (hence one of its names), also, combined with methyl, as one of the chief constituents of oil of winter-green (*Gaultheria procumbens*), and of the essential oil of *Monotropa Hypopithys.*

Salicylic acid may be prepared in different ways. It is obtained by the oxidation of salicin, a nitrogenous body contained in willow bark (cortex salicis); and by the oxidation of saligenin. It is also produced by the heating of oil of gaultheria with potassium hydrate, and the decomposition of the resulting potassium salicylate by means of hydrochloric acid. But it is more simply obtained by the treatment of sodium carbolate with carbonic acid; sodium salicylate is thereby formed, which being decomposed by hydrochloric acid, yields sodium chloride and a thick paste of precipitated salicylic acid. By repeated recrystallizations from hot water, the salicylic acid can be almost perfectly purified.

Prepared in this manner, salicylic acid forms odourless and colourless, or sometimes yellowish, four-sided prisms of somewhat sweetish acid taste.

* Abstract of a paper read before the Austrian Pharmaceutical Society, and published in the 'Zeitschrift des allgemeinen österreichischen Apotheker-Vereines,' April 20, 1875.

It melts at 150° C. and sublimes when carefully heated, without decomposition. Heated rapidly beyond the melting point it is decomposed into carbolic and carbonic acids. In cold water, salicylic acid is only slightly soluble, but it is freely soluble in boiling water, alcohol, ether and glycerine.

Salicylic acid may from its composition be considered to be an oxidation product of benzoic acid, since it contains exactly one atom of oxygen more than benzoic acid, as is shown by the following formulæ:—

$$C_6H_5\,COOH \qquad\qquad C_6H_4\left\{\begin{array}{l}OH\\COOH.\end{array}\right.$$

Benzoic Acid. Salicylic Acid.

Three such isomeric acids, formed by the oxidation of benzoic acid are now known: (1) oxybenzoic acid; (2) salicylic acid; (3) paraoxybenzoic acid. Salicylic acid and its salts differ from the other two by giving a splendid violet colour with solution of ferric chloride. Oxybenzoic acid is obtained by the action of nitric acid in a boiling solution of amidobenzoic acid; paraoxybenzoic acid by the fusing of anisic acid, paracresol, and certain resins, such as benzoin, aloes, etc., with caustic potash. But it is more remarkable that it is formed also by the fixation of carbonic acid on potassium carbolate, in a manner analogous to the formation of salicylic acid by the fixation of carbonic acid on sodium carbolate.

The knowledge that salicylic acid could be readily formed from carbonic and carbolic acids, and that by heat it could be split up again into those two acids, led to the expectation that, similarly to carbolic acid, it would retard if it did not prevent fermentative and putrefactive processes, and act generally as an antiseptic. In this direction Professor Kolbe, of Leipzig, especially has made experiments which have demonstrated that in salicylic acid has been discovered an important and valuable antiseptic. Without smell or notable taste, and not poisonous, in antiseptic power it does not come short, but in many cases even surpasses carbolic acid. Several of these experiments have been described in a former number of this Journal.*

Knopp also has investigated the action of salicylic acid upon vegetation and found that it exercises a very perceptible influence upon the vegetative activity of the chlorophyll cells of the higher orders of plants, and the chromule cells of the lower orders, so long as free acid remains in the solution. But this action disappears as soon as the greater part of the acid becomes saturated by the ammonia which is formed by the resulting decomposition of the albuminous compounds. This agrees with the observations of Kolbe, that the antiseptic action of salicylic acid is not shared by its salts, nor by its isomers oxybenzoic and paraoxybenzoic acids.

Dr. Godeffroy has made, in the laboratory of the Vienna Pharmaceutical School, a series of experiments, chiefly in the direction of the antiseptic action of salicylic acid upon syrups, the results of which essentially confirm those of other authors. The following are some of the details:—

Fifty grams of syrupus mororum were diluted with 50 grams of water and exposed in an open vessel at a temperature of 18° to 22° C. On the other hand, 50 grams of the same syrup and 50 grams of water containing 0·024 gram of salicylic acid were exposed in another vessel at the same temperature; and finally, 50 grams of the syrup and 50 grams of water containing 0·04 gram of salicylic acid were also left to stand in an open vessel. After eight days the mulberry juice diluted with water containing no salicylic acid was completely sour, whilst that diluted with water containing 0·024 gram of acid first became sour after twenty-four days, and the syrup exposed with 0·04 gram of acid on the 8th March had not become sour at the time of writing (20th April).

Fifty grams of syrupus emulsivus [syrupus amygdalarum] were diluted with 50 grams of water containing 0·0475 gram of salicylic acid, and exposed in an open vessel at a temperature of 18° to 22° C. Other portions of similar strength were mixed with 0·11, 0·238, and 0·36 gram of acid respectively, and the whole were exposed in open vessels, together with one portion containing no salicylic acid, on the 8th March. The portion of diluted syrup containing no salicylic acid became sour in four days, that containing 0·0475 gram became sour in ten days; the other portions had not become sour at the time of writing.

Thirty grams of syrupus fœniculi were mixed with 30 grams of water, 0·113 gram of salicylic acid added, and exposed in an open vessel at a temperature of 18° to 22° C. On the thirtieth day it was still completely fresh and good, whilst a similar mixture without salicylic acid became sour in eight days.

Thirty grams of syrupus menthæ were mixed with 30 grams of water and exposed in an open vessel at a temperature of 18° to 22° C. On the tenth day this mixture was sour, whilst a similarly prepared mixture of syrup and water, to which 0·113 gram of salicylic acid had been added, remained quite fresh on the thirtieth day.

The experiments on syrups are still being carried on in the author's laboratory, and he hopes to be able to lay down a general rule for the addition of salicylic acid.

In order to compare the strength of the antifermentative property of salicylic acid with that of carbolic acid, Dr. Godeffroy also made the following further experiments:—

One gram of fresh yeast from a brewhouse was mixed with 13 grams of flour and 10 grams of water into a paste. In five minutes the dough began to swell and in ten minutes had finished rising. This took place more rapidly still in a drying closet at 20° to 30° C.

Other portions of dough were now made in a similar manner, to which varying quantities of salicylic acid and carbolic acid were added with the following results:—

To 13 grams of flour, 10 grams of water and 1 gram of yeast was added:—	gram.	Results.
Salicylic Acid	0·113	Did not swell at all, even after standing for some time at an elevated temperature.
" "	0·056	Did not swell.
" "	0·028	Swelled after 14 hours.
" "	0·014	Swelled after 1 hour.
Carbolic Acid	0·2	Did not swell.
" "	0·15	Swelled after 12 hours.
" "	0·1	Swelled after 1 hour.
" "	0·05	Swelled after 5 minutes.

* *Pharmaceutical Journal*, November 28, 1874, p. 421.

From these experiments the author deduces that 1 gram of salicylic acid is capable of hindering the fermentative action of—

18 grams of yeast	. . . .	Entirely.
36 ,, ,,	. . . .	Fourteen hours.
72 ,, ,,	. . . .	One hour.

On the other hand, that one gram of carbolic acid is capable of hindering the fermentative action of—

5 grams of yeast	. . . . .	Entirely.
7 ,, ,,	. . . . .	Twelve hours.
10 ,, ,,	. . . . .	One hour.

From this it would appear that salicylic acid is more than three times as powerful in its antifermentative action as carbolic acid.

THE ACTIVE PRINCIPLES OF THE OFFICINAL VERATRUMS.*

A Chemico-Physiological Study.

BY CHARLES L. MITCHELL.

Part II.—Chemical.

(*Continued from page* 848.)

The alcoholic solution of resin, previously set aside, was now agitated with successive portions of benzin until freed from oily matter, and then acidulated with 4 fluid ounces of acetic acid, and precipitated in 2 gallons of water. The resin precipitated was separated, and again treated as before. Both acid liquors were mixed, concentrated, precipitated with lime, and the alkaloid extracted in the usual manner. Yield, 100 grains. It contained no jervia.

The resin when separated and dried weighed 320 grains, and corresponded with the resins of veratrum viride and veratrum album; it was quite inert. When freshly precipitated it is slightly soluble in acids, and freely soluble in the alkalies and their carbonates. The benzin washings gave a yield of 4 ounces of oily matter, having a dark green colour.

Several experiments were now tried with the purpose of devising a formula for the manufacture of veratria which would yield as large a percentage, and cost less than the preceding formula. The following was at length adopted:—

℞ Ground Sabadilla Seeds . any convenient quantity.

Exhaust the seeds with q. s. of a menstruum composed of—water, 1 gallon; acid mur., 1 fluid ounce; and evaporate the liquid to a syrupy consistence. To this add milk of lime in slight excess, separate the precipitate, and wash slightly with distilled water, drain and dry. Mix this with a little animal charcoal, powder and exhaust with boiling alcohol. Evaporate the alcoholic solution to dryness, dissolve the residue in dilute sulphuric acid, decolorize with pure animal charcoal, and precipitate with a slight excess of sol. soda. The precipitate when washed and dried will be a fair article of veratria. If it be wanted perfectly pure it may be obtained by dissolving the crude veratria in ether, agitating the ethereal solution with dilute sulphuric acid, and precipitating with an alkali. By this means I have obtained a yield of pure veratria, averaging 225 grains to the avoirdupois pound, and at a very small cost. The ether and alcohol used in this operation may both be recovered by distillation, thus materially lessening the expense.

Although my results with sabadillia were not perfectly conclusive, owing to the small quantity at my disposal, yet I feel almost positive that it is not identical with jervia. I may be able at some future time to settle the matter. This concludes the chemical portion of my paper.

Part III.—Physiological.

Samples of veratroidia, jervia (verat. vir.), veratralbia, and jervia (verat. alb.), were furnished to Dr. H. C. Wood, Jun., who, after fully experimenting with them, forwards the following report:—

"Dear Sir,—In reply to your recent note, I have to thank you for the alkaloids which you so kindly placed at my disposal, and to state that I have performed a large number of experiments with those obtained from veratrum viride, and a few with those prepared from veratrum album. The veratrum viride alkaloids were two in number; one which you labelled *veratroidia*, and a second marked *jervia*. The first of these is undoubtedly the same substance as the material furnished me some years since by Mr. Bullock, under the same name.

"As the result of nearly twenty experiments, I have no hesitation in saying, also, *that your jervia is the viridia of Bullock*. There is absolutely no difference whatever in the symptoms produced; the same general weakness, absence of vomiting or purging, lowering of arterial pressure, and slowing of the pulse, profuse salivation, and finally convulsions, occur in either case. The character of the convulsions caused by viridia is, as I long since called attention to, very peculiar and very constant; I find that 'jervia' produces precisely the same form of convulsions, and am fully convinced of the identity of the two alkaloids.

"In regard to the alkaloids of veratrum album, I am not able to speak so positively. The 'jervia' was only in sufficient quantity for a single experiment, and this was somewhat invalidated by the fact that the drug was dissolved in a very large quantity of alcohol. The jervia of veratrum album appears, however, to be the same as the jervia of veratrum viride.

"The 'veratralbia' I have experimented with to some extent upon frogs; its action is seemingly distinct from that of veratroidia, and, indeed, resembles more closely that of veratria. It is much more powerful than any sample of veratroidia I have ever seen, and acts much more intensely upon the muscles, appearing to be as truly and specially a muscle poisoner as is veratria. I have supplied one or two young men, whom I believe to be in every way competent, with the veratralbia, and expect that you will get, in a few days, a more definite and detailed report from them as to its physiological action."

For a more detailed account of the foregoing experiments on the veratrum viride alkaloids, I refer the reader to a paper by Dr. Wood, now in course of preparation.

These experiments settle pretty clearly the disputed point of the existence of viridia, and prove that jervia is not, according to Dr. Peugnet, a feeble spinal excitant, but, on the contrary, a powerful cardiac sedative and spinal depressant. Peugnet's theory that Bullock's viridia was a mixture, is not only not borne out, but positively disproved by his own experiments. I can give no explanation as to the wide difference between the chemical reactions of jervia (or viridia) as observed by Mr. Bullock and by myself, and can only refer the reader to the negative results of the close examination to which the root was subjected.

Dr. Peugnet's resinoid was next to be examined. The alkaloid had been previously separated from it, and was now tested, as was also the exhausted resin.

Exp. No. 1. (Made with exhausted resin from Dr. Peugnet's resinoid.) Male pigeon. 1.50 P.M., injected ½ grain hypodermically; 2.25, no action; injected 2 grains more, rather quiet; 4.30, has vomited slightly, quiet and rather depressed. Next morning, pigeon was as usual.

The vomiting was very probably caused by the resin not being perfectly free from alkaloid, as in experiment No. 6 the same result was noticed.

Exp. No. 2. (Alkaloid from Dr. Peugnet's resinoid.) Female pigeon. 5.15 P.M., injected hypodermically, with 2 min. sol. alkaloid (unknown strength); 5.20, vomiting; 5.30, very weak on feet, still vomits; 5.45, nearly paralysed, falls on one side, convulsions; 6, paralysed; left until the next morning it seemed to have partially re-

* Read before the American Pharmaceutical Association. Reprinted from the 'Transactions.'

covered; gave 5 m. of solution; 5 min., dead. Slight convulsions.

Autopsy. Heart hard, contracted, empty. Marked congestion and redness of mesenteric vessels.

Exp. No. 3. Was made on myself. Jan. 13th, 3 P.M., took $\frac{1}{8}$ grain exhausted resin of veratrum album; pulse 76. 1 hour. Pulse 80; no perceptible effect; took $\frac{1}{4}$ grain more. 1 hr. 30 m. Pulse 76; no effect; took $\frac{1}{2}$ grain. 2 hrs. 15 m. Pulse 78; took 1 grain; stomach feels mawkish and slightly nauseated. 3 hrs. Pulse 78; took 2 grains. 3 hrs. 30 m. Pulse 80; still slightly nauseated. 4 hrs. Pulse 80. Nausea still marked, relieved at times by eructations of wind. No other result was obtained, and nothing unusual was noticed, except a marked feeling of nausea and indigestion.

These experiments leave no doubt as to the inactivity of the resin of veratrum album when completely deprived of alkaloids. In addition to the few experiments made by Dr. Wood with veratralbia, a number of additional ones were made by both myself and Dr. John R. Haynes, to whom Dr. Wood had kindly referred my samples of alkaloid.

Exp. No. 4 (*J. R. H.*) *Veratralbia A.* May 2nd, 1874, 10 P.M. Full-grown pigeon. Weight, 13 ounces. Pulse 140, to beyond count when frightened (ear to side). Respirations, 58. Temperature, 110°; thermometer in rectum, 5 min. Injected hypodermically $\frac{1}{10}$th grain into thigh. Immediately on placing on table sat tremulously on whole length of legs; nodded; fell on side; gave two or three convulsive movements; emptied rectum. 3 min. Respiration, 116. $3\frac{1}{2}$ m. Heart-beat inaudible; marked opisthotonos; and death at 4 minutes after injection. Pupils unchanged throughout.

Post-mortem. 5 min. after death (temp., 107°). Heart hard, contracted, empty. Lungs, pinkish-white; not congested. Alimentary canal and apparatus normal. Brain and spinal cord rather anæmic. Rigor mortis not yet developed.

Exp. No. 5 (*J. R. H.*) *Veratralbia B.* May 3rd, 3.15 P.M. Pigeon, weight $11\frac{1}{4}$ ounces. Heart-beat 176 to beyond count when agitated. Respirations, 48. Temperature, 110°. Injected into thigh $\frac{1}{10}$th grain. Flew from table across room; fell on floor and hopped on one leg to corners, at first holding up the leg which had received the injection; afterwards, dragging along as if paralysed. 3 min. Respirations very frequent; heart-beats inaudible; slight opisthotonos; and death in 4 min. after injection. Pupils contracted just before death, immediately afterwards dilated.

Post-mortem. 5 min. after death. Had defecated slightly. Temperature, 112°; slight rigor mortis. Heart; right auricle filled with dark blood; left auricle with red blood; ventricles nearly bloodless, hard and contracted. Lungs natural; not congested. Alimentary canal, normal. Brain and spinal cord anæmic.

These experiments were made with the veratralbias *A* and *B*, which had been carefully separated in order to ascertain whether, owing to their mode of extraction, there was any difference between them and show that they are identical.

(*To be continued.*)

THE PHYSIOLOGICAL ACTION OF THE CHINOLINE AND PYRIDINE BASES.*

BY JOHN G. M'KENDRICK AND JAMES DEWAR.

When either quinine, cinchonine, or strychnine is distilled with caustic potash, each of these substances yields two homologous series of bases, named the pyridine and chinoline series. Anderson and Greville Williams have shown that bases isomeric with these are also obtained by the destructive distillation of coal or from Dippel's oil. Greville Williams has also pointed out that chinoline obtained from coal-tar differs in some respects from that got from cinchonine. This suggested to the authors a research to ascertain (1) the physiological action of the various members of the series; (2) whether there was any difference in this respect between the members of the series obtained from cinchonine and those got from tar; and (3) whether, and if so, how, both as regards extent and character, the physiological action of these bases differed from that of the original alkaloidal bodies.

The bases in both series were separated from each other, as far as possible, by repeated fractional distillation. The substance first examined was chinoline (C_9H_7N) obtained from cinchonine. It was employed both as sulphate and hydrochlorate, dissolved in water, and introduced by subcutaneous injection into the animal. The strength of the solution employed in this and in all other instances was one part of the base to twenty parts of water. Its physiological action was tested on frogs, mice, rabbits, guineapigs, cats, dogs, and man; but as the effects were found to be similar in all of these instances, the majority of the observations were made on rabbits. The action of hydrochlorates of the bases distilling off at higher temperatures, including such bases as lepidine ($C_{10}H_9N$), dispoline ($C_{11}H_{11}N$), tetrahiroline ($C_{12}H_{13}N$), etc., was next studied by the same method. The pyridine series was then examined, beginning with pyridine (C_5H_5N) itself, and passing upwards to bases obtained at still higher boiling-points, such as picoline (C_6H_7N), lutidine (C_7H_9N), collidine ($C_8H_{11}N$), parvoline ($C_9H_{13}N$), etc. Lastly, the investigation was directed to the action of condensed bases, such as dipyridine ($C_{10}H_{10}N_2$), parapicoline ($C_{12}H_{14}N_2$), etc.; and the effects of these substances were compared with those produced by the members of the chinoline series and among themselves. So far as could be observed, there was no difference as regards physiological action between bases obtained from cinchonine and others got from tar.

The general conclusions arrived at were—

(1) That there is a marked gradation in the extent of physiological action of the members of the pyridine series of bases, but it remains of the same kind. The lethal dose, however, becomes reduced as we rise from the lower to the higher.

(2) The higher members of the pyridine series resemble, in physiological action, the lower members of the chinoline series, except that the former are more liable to cause death by asphyxia, and that the lethal dose of the pyridines is less than one half that of the chinolines.

(3) In proceeding from the lower to the higher members of the chinoline series, the physiological action changes in character, inasmuch as the lower members appear to act chiefly on the sensory centres of the encephalon and the reflex centres of the spinal cord, destroying the power of voluntary or reflex movement; while the higher act less on these centres, and chiefly on the motor centres, first as irritants, causing violent convulsions, and afterwards producing complete paralysis. At the same time, while the reflex activity of the centres in the spinal cord appears to be so far inactive as not to be excited by pinching or pricking, it may be readily roused to action by strychnine.

(4) On comparing the action of such bases as C_9H_7N (chinoline) with $C_9H_{13}N$ (parvoline), or $C_8H_{11}N$ (collidine) with $C_8H_{15}N$ (conia from hemlock), or $C_{10}H_{10}N_2$ (dipyridine) with $C_{10}H_{14}N_2$ (nicotine from tobacco), it was observed that, apart from differences in chemical structure, the physiological activity of the substance was greater in those bases containing the larger amount of hydrogen.

(5) Those artificial bases which approximately approach the percentage composition of natural bases are much weaker physiologically, so far as can be estimated by amount of dose, than the natural bases; but the kind of action is the same in both cases.

(6) When the bases of the pyridine series are doubled by condensation, producing dipyridine, parapicoline, etc.,

* Abstract of a paper read before the Royal Society.

they not only become more active physiologically, but the action differs in kind from that of the simple bases, and resembles the action of natural bases or alkaloids having an approximately similar chemical composition.

(7) All the substances examined in this research are remarkable for not possessing any specific paralytic action on the heart likely to cause syncope; but they destroy life, in lethal doses, either by exhaustive convulsions or by gradual paralysis of the centres of respiration, thus causing asphyxia.

(8) There is no immediate action on the sympathetic system of nerves, although there is probably a secondary action, because after large doses the vaso-motor centre, in common with other centres, becomes involved.

(9) There is no appreciable difference between the physiological action of the bases obtained from cinchona and those derived from tar.

THE OCCURRENCE OF ORGANIC FORMS IN CONNECTION WITH CONTAGIOUS AND INFECTIVE DISEASES.*

BY J. BURDON SANDERSON, M.D., V.P.R.S.,

Jodrell Professor of Physiology in University College, etc.

Lecture III.

Specific Contagia.

In the last lecture, we entered on the consideration of the question, whether or not, in those cases in which fever is produced by a poison of septic origin, the organisms which associate their life and development with all putrefactive processes are concerned in the pathological phenomena which manifest themselves. It was shown, on the ground of experiment, that, although pyrogenic liquids in the crude state are septic, and, therefore, contain bacteria in greater or less numbers, it is possible to obtain from them a material of great activity, *leaving behind the microphytes.* In stating this fact, I pointed out that it would afford no ground for denying the influence of bacteria in the production of the morbific material; for, although they may not themselves constitute it, there is nothing in the fact observed which makes it less probable than before that they are concerned in those chemical changes of which its presence is one characteristic. At the close of the lecture, I drew special attention to a fact of great moment, namely, that, in my pellucid pyrogenic liquid, the active principle, although apparently in solution, is really particulate, for it can be separated by an appropriate mode of filtration (filtration through a "porous cell").

To-day we pass to a subject which must be kept apart from the other—that of the relation of microphytes to specific infections. The two questions are distinct by nature, and consequently the modes which have to be employed in their investigation are necessarily different. It is, therefore, desirable to keep them separate. In fever, we have to do with a process—an aggregate of functional disorders, all of which have their seat in the organism. In contagion, we have to account for its effect on ourselves, and also (what is more difficult) for its behaviour outside of us—the wonderful fact that it preserves itself for long periods, and is conveyed to immense distances quite independently of its ultimate destiny.

The doctrine that microphytes have to do with the process of contagion is based on two sorts of observations, viz., those relating to the physical characters of contagious liquids, and those relating to the existence of organisms of characteristic form in them. As regards the physical characters of contagious liquids, the fundamental fact is that contagium is *particulate.* I do not hesitate to use this word, for there is no other which answers the purpose. It stands for the general result of observations made by Chauveau as to the non-diffusibility of the infecting part of a great many contagious liquids, particularly those of small-pox, vaccine, glanders, the so-called small-pox of sheep, or sheep-pox. The method employed by Chauveau in these investigations is now so well known that I need only advert to it very shortly. As a link in the chain of evidence on which the notions we now entertain as to contagium are supported, it is too important to be omitted. The method, like that of which in last lecture we considered the application to the investigation of the fever poison, is one of mechanical analysis. A liquid known to be actively virulent is placed at the bottom of a small test-tube, which stands upright on a foot, or is otherwise supported in the same position, care being taken to avoid the slightest contact between the liquid and the sides. Water is then allowed to flow over the surface of the liquid until it forms a layer a few lines in thickness. The result is that, if the liquid remain absolutely still, diffusion takes place between the liquid and the water. The soluble salts pass into the water, along with a quantity of albumen: everything which is particulate remains below, everything that is diffusible rises. The process differs from that of diffusion through a membrane in this respect, that, whereas in the "diffusion cell" bodies which are very slightly diffusible, such, *e.g.*, as albumen, pass through the membrane in extremely small quantity, so that practically they may be said to remain behind, in the present case the only constituent which remains at the bottom consists of particles which, although they are small enough to pass readily through filtering paper and act so little on light that they do not render the liquid turbid, can yet be seen under the higher powers of the microscope. Hence, if the contagium is particulate, it will be found exclusively in the lower layer; if diffusible, it will be in the surface layer of water, albumen, and salts. Experiment showed, as regards all the contagia I have mentioned, that it remained below; and, therefore, was insoluble and indiffusible.

These experiments were made in 1868-9. I became acquainted with them when spending some time at Lyons in the latter year, and afterwards repeated them in London in their application to vaccine. I had previously (in 1866) made analogous experiments on the contagious liquid of Rinderpest, but by another and very inferior method. I had introduced a liquid of known contagiousness into an ordinary diffusion cell, and had observed that the active part did not pass through the parchment-paper septum. This is a bad method, because in this kind of diffusion the albuminous compounds, which are very slightly diffusible, are stopped by the septum; so that it might be objected that the toxic agent was contained in the albumen, not in the particles. Indeed, a blunder of this sort has been very recently promulgated by a French writer, M. Onimus.

On this inference as to the particulate nature of contagium, I founded in 1870 an *à priori* argument in favour of the probability of *contagium animatum*—that is to say, in favour of the doctrine that the property of contagiousness as manifested in contagious morbid products is associated with the presence in such products of particles *which possess a life which is not that of the tissues of the human or animal subject of disease.* If contagium be conveyed from place to place and maintain its activity in the form of particles, those particles must consist either of bits of protoplasm or of living organisms; for those are the only sorts of particles of which we have any indication in contagious liquids.

Now, considering that of all perishable things protoplasm is among the most perishable—so much so, that no living particle of our bodies can be abstracted from its place in the organism, even for five minutes, without dying and being disintegrated—it appeared to me quite out of the question to suppose, as Dr. Beale had suggested, that the particles could be of this nature, consistently with the astonishing power which they evidently possess of retaining their activity for such long periods, in spite

---

* Lecture delivered at Owens College, Manchester; reprinted from the *British Medical Journal.*

of their being subjected to enormous varieties of moisture, temperature, and all other conditions. And considering that life—*i.e.*, organization—is the only condition whereby a body of chemically unstable composition is enabled to hold its own against such disintegrating agencies, I thought then, and I still think, that the only possible explanation of this fact of the persistence of contagium was to suppose its particles to be living. Then at once the question arose—"What sort of life is it that they possess?" Two facts help us to conclude in favour of the group of organisms I described in last lecture; first, they are the smallest and simplest of known organic forms; and, secondly, they possess the wonderful property of passing into a state of persistent inactivity or latent vitality, in which they perform no function, but can be at any moment wakened up into active function whenever they are brought under favourable circumstances. If I am asked what ground I have for the statement, that bacteroid microphytes possess the property of latent persistence, I will content myself with drawing your attention to the undisputed facts relating to the inoculation of "test-liquids." If I find that a particle of dust which has remained on the ceiling of the room for some time, when added to a solution of ammonic tartrate, determines an enormously active vegetation of bacteria in it, I find it difficult not to suppose that the particle of dust contains living material; and inasmuch as I know that, if I examined it under the highest powers, I should see nothing which I could recognize as vegetable by any vital manifestations which it would present to me, I am compelled to express the result of the experiment in some such terms as I have used. Particles are there, which, so long as the dust remains on the ceiling, undergo no change, manifest no process. You may object that I have no proof that the dust contains anything living. True; but I have proof that it contains that which produces life, and express this state of things; viz., the absence of manifestations of life, on the one hand, and, on the other, the fact that the stuff in question possesses the power of impregnating something else which before was barren, by saying that the dust possesses latent vitality.

I have now to run over, as briefly as possible, the cases in which observations have been made as to the presence of organisms in contagious products. As vaccine and small-pox have been already mentioned, I will refer to that subject first.

The earliest published observations as to the existence of microphytes in the infective liquids of vaccine and small-pox were those of Hallier and Keber (1868), both of which were made with bad instruments, and attracted less attention that they would otherwise have done from the speculations with which they were associated. My own description of the organisms of vaccine appeared in an appendix to the twelfth report of the medical officer of the Privy Council in 1870. About the same time, but quite independently, they were much more completely investigated by Cohn, the eminent professor of botany at Breslau. The description of Cohn agrees entirely with mine: a fact which I think important enough to mention, on account of its bearing on certain statements recently published by Dr. Beale, to which I must refer immediately.

Cohn has given to the organism seen in vaccine the designation of *Microsphæra vaccinæ*. In fresh vaccine, it consists, according to his description, of minute spheroids grouped in couples or isolated. If a preparation of lymph be observed under the microscope on the warm stage, these particles divide repeatedly, and thus resolve themselves into chaplets. By this fact, as well by their chemical reactions, they are easily recognized as micrococci. There is, I think, no particular reason to doubt the accuracy of the observation, discovered as it was in the first instance by observers working quite independently of each other, and in ignorance of each other's results. I was, therefore, rather surprised that, in a recent work on 'Disease Germs,' Dr. Beale should have criticized my very brief description of these organisms, and particularly the woodcuts with which it is illustrated, in such strong terms as he has employed. Be it remembered that I have not asserted that the particles in question are "disease-germs" at all. All that has been stated is, first, that they are independent organisms, and, secondly, that they are to be observed in fresh vaccine.*

Shortly before the appearance of Cohn's first paper, another Breslau observer—a pathologist and hospital physician, not a botanist—published a short communication founded on the microscopical examination of the skin in persons who had died of small-pox, in which he stated that he had found the lymphatic vessels of the cutis plugged with a granular mass which exhibited all the characters of micrococci. These lymphatic vessels were met with for the most part in the tissue of the corium underneath and around pustules in various stages of advancement. Here, in some cases, they occurred so constantly, that they could be found in every vertical section of the skin which comprised a pustule, though they were absent in others.

This statement being founded on a considerable number of cases is probably well worthy of confidence. It is to be noted with respect to it, that the appearances in question were observed only in cases which terminated early in the disease, *i.e.*, before the seventh day. In more advanced cases, the infiltration of the tissues and the consequent impletion with the cellular products of inflammation, rendered it impossible to make out with certainty whether the vegetations were present.

The two facts you have before you, viz., the existence of organisms in vaccine matter, and the occurrence of similar organisms (not ascertained to be identical with the other) in the lymphatics, suggest the probability of their having to do with the morbid process, but cannot be accepted as an adequate proof that they possess the property of reproducing or propagating the disease. For the establishment of such proof with respect to any contagium, it would have to be shown either that when deprived of its organisms, though otherwise unaltered, it is deprived of its activity; or that when the organisms are introduced alone, they manifest the contagious property of the liquid or tissue from which they were derived. An imperfect approach towards the first of these demonstrations was made in Chauveau's experimental investigations; for it was shown that many contagious liquids lose their activity when they are deprived of the suspended particles in which whatever organisms they contain are included. The second demonstration must, with our present means of observation, be regarded as impossible, on the ground that the bodies in question are so minute that there is not the slightest prospect of our being able to separate them in anything like purity.

---

* For the information of the reader, I transcribe the passage referred to. "The drawing given by Dr. Sanderson conveys no idea of the actual appearance of the matter represented. A few minute circles may be made to indicate very fairly the appearance of microscopic fungi; but they are no more like the particles of vaccine lymph, or any contagious poisons, or any kind of living matter known, than an oil-globule or an air-bubble is like a white blood-corpuscle or a pus-corpuscle. Such illustrations only help to retard investigation, and to convey erroneous ideas regarding the character of the matters referred to" ('Disease-Germs,' second edition, p. 237). There can be no doubt that my drawings are not like those of Dr. Beale; but that they give a true notion of the object represented, the reader may satisfy himself by comparing them with those of Professor Cohn: the resemblance between them is complete. No doubt, Dr. Beale, regarding us both as "blind leaders of the blind," would find both representations alike faulty. The explanation of the discrepancy is obvious. I had before me certain spheroidal bodies of extreme minuteness, which I represented in my woodcuts in the usual conventional way—*i.e.*, by what Dr. Beale calls "minute circles." Professor Cohn's figures are of the same character. Dr. Beale had before him "bioplasts" of various shapes and sizes, all admirably drawn (see 'Disease-Germs,' fig. 66). It could hardly be expected that the pictures should be like each other.

The Pharmaceutical Journal.

SATURDAY, MAY 1, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SALE OF VERMIN KILLERS.

SEVERAL correspondents writing recently on the sale of vermin killers appear to be under a misapprehension as to the actual requirements of the Pharmacy Act. In one instance, the writer of a letter, signed "A. A.," desired to be allowed to call attention to what he imagines to be an inaccuracy in the Act that has led to the practice of omitting to take the address of purchasers at the time of sale.

The inference that such an inaccuracy exists seems to have arisen from looking at the form given for registration in Schedule F, without at the same time considering the terms of the 17th section of the Act. In order to make this clear we reproduce the headings of the form as given in Schedule F:—

Date.
Name of Purchaser.
Name and Quantity of Poison sold.
Purpose for which it is required.
Signature of Purchaser.
Signature of Person introducing Purchaser.

In these headings our correspondent considers that no provision is made for registering the address of the purchaser, and he maintains that consequently this schedule is not drawn up in accordance with the 17th section of the Act, which provides that on every sale of articles in Part 1 of Schedule A, the sellers shall, before delivery, make or cause to be made an entry in a book to be kept for the purpose, stating *in the form set forth in Schedule F*, the date of the sale, *the name and address of the purchaser*, the name and quantity of the article sold, and the purpose for which it is stated by the purchaser to be required. This statement sets out so clearly what is to be done by the seller, and describes so fully the nature of the entries to be made in the first four columns of the form set forth in Schedule F, that it is only by omitting to read the 17th section of the Act the necessity for registering the address of the buyer can be overlooked.

Schedule F must not be regarded as specifying what details are to be registered but merely the form in which those details are to be registered. According to the 17th section, among those details the address as well as the name of the purchaser is specified, and they are clearly intended to be entered in the second column of the form given in Schedule F.

It might, perhaps, have been better if the heading of this second column had indicated the necessity of registering the address as well as the name of the purchaser; but even as it stands there is not the slightest ground for doubting that this is necessary. In order to obviate the possibility of such an oversight occurring we would suggest that there should be a foot-note printed on the forms of poison registers, pointing out that the address of the purchaser is to be entered with his name in the second column. It was only in regard to this particular that in the late Wolverhampton case there was any deviation from the requirements of the Act, and in that case the seller of the poison appears simply to have been misled by the heading of column two in the form just in the same way that our correspondent "A. A." has been.

We do not pretend to suggest that, if this requirement of the Act had been complied with in the Wolverhampton case it would have been of any avail in preventing the attempt at suicide. Possibly no thoroughly efficient means could be devised for preventing people so disposed from endeavouring to poison themselves, nor need we occupy ourselves with this question. Indeed, the object of the Pharmacy Act can scarcely be assumed to extend so far as this, but rather to aim at preventing the retail sale of poisonous articles indiscriminately by persons who have no special knowledge of their dangerous character.

This leads directly to the consideration of some questions put by another correspondent signing himself "MURICIDANE." What, he writes, is the value of obtaining the signature, name, and address of the purchaser, or of a witness known to both vendor and purchaser? Certainly this proceeding cannot be supposed to operate more than partially in preventing suicide, nor is it to be supposed that people will always be more careful in using poisons because they have signed their names in a book. But in the event of any accidental or intentional poisoning, the registration of the sale as required by the Act furnishes a ready means of tracing the person who is to blame. As regards the chemist, who is the only legitimate vendor of such articles, the registration is, however, of especial value in cases of poisoning, inasmuch as the production of the duly filled up register at once renders him blameless in the eye of the law.

This view of the matter is, we believe, sufficiently appreciated, and consequently there are many who would be inclined to concur with our correspondent "MURICIDANE," in thinking the poison regulations "a vexatious absurdity, giving trouble to chemists and allowing domestic pests to increase."

Another correspondent, signing himself "CRITIC," writes to say that previously to reading the report of the Wolverhampton cases, he was unaware that it was necessary to register the sale of the poison used in that instance, especially as it is openly sold without any such precaution by oilmen and grocers. In illustration of this, he refers to the case reported last week, in which the same poison was obtained from an oil-shop, and he very justly points out that this distinct infringement of the law was wholly disregarded, and that the Coroner's remarks as to the sale of such poison indicated a total misconception of the law.

The illegal sale of poisons is indeed the main complaint of all the writers who have addressed us on this subject, and certainly there seems to be much ground for the dissatisfaction with which chemists and druggists find themselves liable to restrictions in selling poisonous articles that can be obtained with greater facility from oilmen and grocers. As regards vermin-killers, especially, it is surprising that there should still be any uncertainty as to the conditions under which they are to be sold if they contain any of the poison in part 1 of Schedule A. At the time when it was decided that these preparations should be included in Part 1 of the poison schedule every endeavour was made to bring the fact within the cognizance of the entire trade, and a circular was sent with that object to every registered chemist and druggist in the kingdom. On that point, therefore, no doubt should exist. It is equally surprising that magistrates and coroners should so constantly ignore the illegality of the sale of poisons by persons not duly registered as chemists and druggists, and that while local authorities prosecute chemists and druggists, as in the Wolverhampton case, for a slight omission, they should altogether abstain from taking steps against persons who utterly set the law at defiance and disregard it entirely.

PHARMACY ACT FOR QUEBEC.

Two months since we were enabled to state that an Act for regulating the practice of pharmacy in the province of Quebec, in the Dominion of Canada, had been passed by the local Legislature. The Act is to come in force this day (May 1st), after which date it will be illegal for any but a "licentiate in pharmacy" under the Act either to sell certain poisons mentioned in the Schedule or to engage in the dispensing of prescriptions within the province. The poisons are: arsenic and preparations, prussic acid, tartar emetic, metallic cyanides, aconite and preparations, opium and preparations (except paregoric and syrup of poppies), essential oil of almonds (unless deprived of prussic acid), corrosive sublimate, cantharides, savin and its oil, ergot of rye and preparations, strychnine and all poisonous vegetable alkaloids and their salts. It will also be unlawful to keep or sell any of these "poisons," unless the covering be distinctly labelled on a black label with the word "poison" and the name and address of the seller. Further, "poison" is not to be sold to a person unknown to the seller, unless introduced by a person who is known, and an entry is to be made of every sale of a poison, setting forth the date of sale, name and address of purchaser, name and quantity of the article sold, and the purpose for which it is stated by the purchaser to be required. This entry is to be certified by the signature of the purchaser, and the person, if any, introducing him.

The Act makes it illegal for a "licentiate in pharmacy" to employ any unregistered "clerk" or "apprentice" in the sale of poisons or dispensing of medicines. Previous to being bound and becoming registered as a "certified apprentice" the youth must pass a "preliminary" examination in the English, French, and Latin languages, and arithmetic; he must also produce evidence of a good moral character. To become a "certified clerk," the "certified apprentice" must pass a "minor" examination; whilst to become a "licentiate in pharmacy" the "certified clerk" must pass a "major" examination, and produce evidence that he has served at least four years in a drug store and has attended two courses of lectures on materia medica, two courses on chemistry, and one on botany. The examination fees are to be two dollars for the "preliminary," five dollars for the "minor," and ten dollars for the "major;" one half being returned in the event of the candidate being unsuccessful. Besides these fees each "licentiate" will have to pay an annual fee of five dollars to the Pharmaceutical Association of Quebec, which is entrusted with the carrying out of the provisions of the Act; the "clerks" will have to pay an annual fee of three dollars, and the apprentice one of one dollar. Non-payment of these annual fees is to be followed by removal of the defaulter's name from the register, and his loss of privileges until it has been restored after payment of a fine.

SCHOOL OF PHARMACY.

It will be seen, by reference to the advertisement of the School of Pharmacy of the Pharmaceutical Society of Great Britain, that Professor Bentley will commence his course of Lectures and Demonstrations on Systematic and Practical Botany, at the Gardens of the Royal Botanic Society, in the Regent's Park, on Friday morning, May 14th, at eight o'clock. These Lectures will be continued on the succeeding Saturday and Friday mornings till the end of July.

DEATH OF AN HONORARY MEMBER.

At the sitting of the Royal Academy of Sciences of Vienna, on the 15th April, the President announced the loss to the Society that day, by death, of its General Secretary, Dr. Anton Schrotter. Dr. Schrotter was also one of the Honorary Members of the Pharmaceutical Society of Great Britain, having been elected in 1862.

It is announced that the gentlemen whom the Council of the Royal Society has decided to recommend for election as Fellows of the Royal Society, at the meeting in June next, are Messrs. W. Archer, J. R. Bennett, D. Brandis, J. Caird, J. Casey A. Dupré, J. Geikie, J. W. L. Glaisher, J. B. N. Hennessey, E. Klein, E. Ray Lankester, Nares, R. S. Newall, W. C. Roberts, and Major-General Scott.

Transactions of the Pharmaceutical Society.

BOTANICAL PRIZE FOR 1876.

A Silver Council Medal is offered for the best Herbarium, collected in any part of the United Kingdom between the first day of May, 1875, and the first day of June, 1876; and should there be more than one collection possessing such an amount of merit as to entitle the collector to reward, a second prize, consisting of a Bronze Medal, and also Certificates of Honour and Merit, will be given at the discretion of the Council. In the event of none of the collections possessing such an amount of merit as to warrant the Council in awarding Medals or Certificates, none will be given.

The collections to consist of British Flowering Plants and Ferns, obtained in a wild state, and arranged according to the Natural System; the collections to be accompanied by lists, arranged according to the same system, with the species numbered.

The collector to follow some work on British Botany (such as that of Babington, Hooker, or Bentham), and to state the work which he adopts. The name of each plant, its habitat and the date of collection, to be stated on the paper on which it is preserved.

Each collection to be accompanied by a note, containing a declaration, signed by the collector, and certified by his employer, or a Pharmaceutical Chemist to whom the collector is known, to the following effect:—The plants which accompany this note were collected by myself from wild plants, between the first day of May, 1875, and the first day of June, 1876, and were named and arranged without any assistance but that derived from books.

In estimating the merits of the collections, not only will the number of species be taken into account, but also their rarity or otherwise, and the manner in which they are preserved; and should a specimen be wrongly named, it will be erased from the list.

The collections to be forwarded to the Secretary of the Pharmaceutical Society, 17, Bloomsbury Square, on or before the first day of July, 1876, indorsed "Herbarium for Competition for the Botanical Prizes." After the announcement of the award, they will be retained one month, under the care of the Curator of the Museum, for the inspection of persons connected with the Society, and then returned to the collectors, if required.

No candidate will be allowed to compete, unless he be an Associate, Registered Apprentice, or Student of the Society, or if his age exceed twenty-one years.

NORTH BRITISH BRANCH, EDINBURGH.

The sixth and last scientific meeting of the present session took place in the Society's Rooms, 119a, George Street, on Tuesday evening, 27th April.

Mr. Gilmour, President, in the chair.

Dr. F. W. Moinet, Lecturer on Materia Medica, read a paper, of which the following is an abstract:—

There has been a tendency I am sorry to say, even amongst those of the medical profession, to speak lightly of therapeutics or the value of medicine in the treatment of disease. Hence the reason of my choosing, as the subject of my lecture this evening, the curative power of medicine,—to try and show you that drugs in the physician's hands are powerful agents for good or evil to his patients, as he uses them with knowledge or abuses them through ignorance. But although ignorance in the physician is no doubt, in some cases, the cause of the failure of a medicine to restore a patient to health, or to alleviate the symptoms of disease and allow nature to work a cure, either on account of an unsuitable drug being administered or from the physician having failed fully to appreciate the symptoms and trace them to their cause, still, I am happy to say, I do not believe that ignorance in the physician is to blame so much for want of faith in our healing art, as is the fact that the science of therapeutics is, so to speak, still in its infancy, and that too much is expected by the public from the administration of drugs. Keeping the first of these facts well in mind, and knowing thoroughly how far we can depend on drugs in the treatment of disease and for the alleviation of suffering, will prevent frequent disappointment both to ourselves and patients, and save often unnecessary blame being thrown on the physician. For a physician who has unreasonable confidence in the power of remedies does as much in an honest way to bring our science into derision as the quack who, without faith himself, tries to persuade the ignorant public that his nostrums and specifics can cure every disease under the sun, from toothache to consumption. Not less injury does the physician who ought to know better, but who sneers at drugs and yet uses them, content to take credit to himself when successful, but ready to blame the medicine if the result is not in accordance with his expectations, forgetting that the action of a drug is certain, whereas his reasoning as to the nature of the disease and the selection of the remedy may be, and often is, fallacious on account of the difficulties in many cases of making a correct diagnosis, and an imperfect knowledge of their mode of action. I have said that the science of therapeutics is still in its infancy, and so it is. Although drugs have been administered from time immemorial for the cure of disease with a spell muttered over them, or still later on the more rational grounds of their ascertained effects from former experiences and experiments, it is only very lately that it has been founded on a proper basis of physiology and chemistry; and as these sciences are in anything but a mature condition themselves, is it too much to expect that one so dependent on them should be more advanced? Considering, however, the progress that has been made of late years I think we are entitled to expect quite as brilliant a future for therapeutics as we do for any other branch of medicinal study. But the problems of therapeutics are not easily solved either by a careless or random experience. This we constantly see in the fate of vaunted new remedies which act wonders, or at least are said to, but which so seldom bear out their good character under the test of experience or some newer rival appearing, showing, as your President remarked in his able opening lecture, "That sound theory should be the outcome of proper observation and deduction, and then the object of careful and proper experiment;" in plain words, that the cart should not be placed before the horse.

After showing the difficulties in the way of solving therapeutical problems on account of the varying constitution of individuals and of diseases on the one hand and of medicines on the other, Dr. Moinet went on to show that prescribing must therefore never degenerate into a matter of routine, but each case must be studied on its own merits, otherwise treatment would be purely haphazard, and so oftener wrong than right. He continued, Another point which I need hardly mention, perhaps, but which affects nearly the reputation of therapeutics, is to make a correct diagnosis before prescribing, to discover what the disease or disorder really is—a matter not always of very easy accomplishment. So that you see the difficulties are not few in the way of administering remedies appropriate to the disease, which should make us very careful before judging rashly of the failure of a medicine when the failure may be our own. In which case, naturally, the unfortunate prescription gets the blame, and the science of therapeutics is the scapegoat.

This, however, might be prevented if we have the first quantity of the problem known by the disease, by the physician recognizing just how much or how little to expect from his prescription; and, in any case. I think it but right that he should not indulge his patients' hopes by over-valuing its powers. At the same time he must be careful not to deprecate it, for faith is an important adjuvant to any remedy, and its absence will even counteract the benefit of some. In want of attention to these points and also want of perseverance either in doctor or patient might be found the cause of many failures. But the one to which I particularly wish to draw your attention is, how far we can depend upon and how much expect from the curative power of medicine. Ignorance of this being the chief reason in my mind, although not by any means the only one, for the little estimation that therapeutics are held in by some both in and out of our profession.

Dr. Moinet then went on to explain the curative power of nature. The healing of a wound is a natural and spontaneous act, as is also the meeting of the ends of a fractured bone. But the surgeon can bring together the edges of a wound with sutures and keep the ends of a fractured bone in apposition by means of splints and other appliances, so as to put the parts in a more favourable condition for nature to act her part. In the same way and for the same reason the physician administers his drugs in various diseases and disorders, being quite aware at the same time that in many cases nature of herself would be sufficient to work a cure. But he interposes, and wisely, I think, to assist her, and so in many cases to prevent further mischief, hasten the cure, preserve the patient's strength and alleviate pain, which in some cases means to save life. Take a case of typhus or scarlet fever. The physician uses means; they need not all be drugs, but as tending to the cure are no less remedies by which he assists nature in the elimination of the poison, keeps down the temperature, soothes restlessness and delirium by appropriate medicines, and so in acting in concert with and assisting nature, he saves the patient's strength, mayhap shortens the fever's course, prevents the occurrence of sequelæ or complications which of themselves are often fatal, and in this way frequently preserves life and always alleviates pain and suffering. In thus assisting nature you save your patient's life, and what more can you do or expect from a drug, whether you call it the effect of the medicine, which it undoubtedly is, or its power of assisting nature?

Dr. Moinet then explained the specific or elective action of drugs. This specific action, however, he said, does not mean, as some imagine it does, that drugs are infallible remedies, as they are too frequently vaunted to be, but simply that they act upon the diseased part directly and beneficially when properly chosen and suitably administered. But you must not confound this specific action of a few remedies, and which is only applicable to some cases, with the principle of homœopathy, viz., "*Similia similibus curantur.*" After reviewing the doctrines of homœopathy, Dr. Moinet said that being irrational in theory they must be wrong in practice. The dogma "*Similia similibus curantur,*" known and recognized in all ages as possessing a certain limited value, has most signally failed when propounded as an exclusive principle for the selection of remedies. It is one of those dangerous fallacies, especially to the ignorant, having a basis of partial truth; but to rest upon this one imperfect law a foundation of a system of therapeutics is practically as absurd as to try and cure all diseases by one medicine.

Dr. Moinet then showed the use of medicine in chronic and incurable disease, how often it is able to prolong life and to restore, even if not permanently, a useful degree of vigour. The greatest dangers of typhoid fever, dysentery, and some forms of cardiac and renal dropsy are greatly diminished by the use of medicine. By the same means and in the same diseases the natural process of cure is often expedited, for whatever limits pathological changes must shorten and simplify the steps which lead back to health. In many diseases the secondary lesions cause the danger to life, and by acting on them when the primary lesion is incurable, we often can prolong life so much that the patient has time to die of some other disease. Independent, however, of their influence on diseased tissues, medicines are of infinite service in lessening the violence of symptoms or pain, for oftentimes, by their intensity alone, the powers of life become enfeebled and at last succumb.

After showing the reasons why in many cases diseases were and must necessarily be incurable, Dr. Moinet said: But if chemistry and pathology can discover the exact changes in medicine, then, if therapeutics can do nothing, there will be some reason for blame. But the part is not greater than the whole, and until the art of medicine has reached a higher state of development, the branch of therapeutics must attend her in her more lonely course. But this will not continue, for the great progress that has been lately made in material science gives us good grounds to hope for the future that the physician may practise his art by the light of pure science, with a confidence and certainty in no degree less than that of the physicist, and to attain this we must be content to work patiently and laboriously, both as pharmacist and physician, in search of truth, knowing that however little, if honest, our work will help to this end, although we may never live to see it. I hope I have shown you, although thus briefly, that while some diseases are necessarily incurable others are curable by drugs, which support, restrain, and remove impediments from nature's path, and thus life is prolonged or saved. You will see that medicines are not inert or feeble in the treatment of disease, or of doubtful service in the physician's hands; but that to avoid just reproach we must have definite and exact ideas of what they can do and what they cannot do, and not deceive either ourselves or others with vague or unreasonable hopes and expectations. And I think, and I trust you will agree with me when I venture to say, that the medical man or woman, as the case may be, who either through ignorance or otherwise neglects to make a proper use of the remedies we possess, does neither justice to his patient nor to the profession to which he belongs.

But, gentlemen, death is the natural termination of life. Still, I believe there is not one here who is such a fatalist but that when ill he would send for a physician, or in bodily danger that he knew of but would try to avoid it, and rightly. But the need of the physician and his drugs is not to avert the inevitable, but rather to avert the consequences of man's own ignorance and folly, but for which our profession were almost at an end. Hence we must always remember that there is a higher duty, not only of the physician, but also of individuals, viz., to prevent disease, for which purpose they must work in concert. The physician to show the way, the public to follow, and, if necessary, the State to enforce it.

A vote of thanks to Dr. Moinet for his interesting paper was proposed by the Chairman, and carried with acclamation.

The following valedictory remarks were then made by the President (Mr. Gilmour):—

"Gentlemen,—As you are aware, this meeting brings us to the close of another session, and according to a good and proper custom I have much pleasure in reviewing some of the work which has been accomplished by us in our scientific meetings during the past six months. Whether we look at this session in the communications which have been before us at these meetings, or in the large attendance (some evenings the hall being quite filled) and the great interest manifested in them, we have alike cause I feel assured to be satisfied. In no former session have the communications exceeded in interest those of the present, and I think I may also safely say that never before have the audiences been so uniformly large.

"The subjects brought before us have all been exceedingly practical in their nature, and in every case have been of more than mere passing interest to us. Where all have been good, it would be invidious to make distinctions, but I can scarcely help calling your attention to the number of papers which have been before us this session, containing invaluable results and conclusions in original research. First on the list in this class, was Dr. Stevenson Macadam's investigation on the action of aërated waters on lead, with more immediate reference to the presence of lead, or the possibility of its presence, in the aërated waters as commonly manufactured and sold, and we must all yet remember the interest which Dr. Macadam infused into his audience in the graphic way he described the various processes in which he investigated the subject and arrived at his conclusions, and the interesting experiments with which he accompanied his communication to us. Following this at another meeting was a most able and exhaustive analysis of chrysarobine, by Professor Attfield, communicated by Mr. Baildon, a paper which we think will be followed by more valuable results as attention is called to it through the pages of the *Pharmaceutical Journal* and other ways. Dr. Macadam was again next on the list with a concluding paper on his investigations on the composition of milk; and as Dr. Macadam has done, more probably to adjust a proper standard for the testing of milk than any other man in this country, this, of itself, was sufficient to guarantee the importance of the communication. Lastly, we had Dr. Craig with a series of exhaustive investigations on the action and effects of resin of aloes, a communication so lately before us that it must yet be fresh in the minds of all, and which appeared only the other week in the pages of the Journal, so that it is unnecessary I should at present refer to it further. Of the lecturers I need only remind you that we had an old friend in Mr. Sadler, who gave us a most interesting lecture on fungi, and I need not remind you that to-night we have a new friend in Dr. Moinet, whom I am sure from the value and interest of his paper we shall be glad soon to welcome back again with another on the same or a similar subject. Amongst the remaining contributors we were all more than pleased to welcome the presence both of Mr. Mackay and Mr. Baildon; the former finding still time amidst all his multifarious, and too often toilsome, duties for the Society in Scotland to share in these labours also; the latter, though ceasing, I am sorry to say, from some of the more active duties, still, however, manifesting his interest in these meetings both by his help and presence. It is fitting, I think, that notice should also be taken here of the many interesting and valuable contributions to the museum and library made during the session, both by the parent Society and private individuals. Of these none have been more princely in their nature or useful in their character than those presented by our old and warm friend, Mr. D. R. Brown. With probably a single exception, which I need not mention, there is not a man who by word and deed has done more for the Society in Scotland, and I am sure there is not a heart in all this meeting to-night but warms at the very mention of his name. Well do I remember years ago when advocating and scheming and labouring for a museum and library such as he thought was required by the Society, and such only as he would be content with, namely, one that would not be without one single specimen or book of reference which it was thought the student of science could by any human possibility at all require, he was sceptically told that such an institution would not be used or appreciated by one young man in a hundred. Well do I remember how impressed I was with the answer, 'That for the sake of that single man it was still required, and for his sake worth all that it would cost.' It was the answer of one who had all his life been a student, and one who, therefore, understood and sympathized with all a student's trials and difficulties. But I would be sorry indeed for many reasons to think that the real earnest hard-working students amongst us were so few in numbers as here indicated. I cannot think that the love of knowledge for its own sake, as well as for all the many advantages and inducements which it ever holds out to its possessor, can have so entirely lost its charm as to reduce the number of such students even to a minimum. I firmly believe, on the contrary, that ever as the standards drop from the hands of the pioneers of pharmacy as they have dropped by old age from the hands of Mr. Brown, or more sad still, by early death from the hands of Mr. Hanbury, so will there ever be a band of noble competitors, ready and eager to raise them again in emulation of the deeds of their predecessors, a band all the more able and all the more eager from that very help so generously accorded them by such men as Mr. Brown or Mr. Hanbury in their early student struggles. And one of the greatest incentives, I think, for every student next to such a kindly interest and sympathy felt in them by their elders in age and wisdom,—an interest I am glad to say often extending itself to active deeds,—is the incentive of noble example itself. Probably I should place this first, for whilst it is the heritage of all, it is peculiarly the heritage of the most friendless and poor; of him who, without help or sympathy is struggling bravely on through difficulties, through obscurity, it may be, as it has often been in the past, through poverty itself. It is, I have often thought, one of the grandest and most benignant traits of our common humanity, that wisdom in the sire does not necessarily, like many other qualities, indeed, I might say does not often, perpetuate itself in the son, and even though it did, that there is a time in the life of the child, both of philosopher and boor, of prince and peasant, in which they stand on the same level, and from which they must start to meet the same trials and difficulties, and, if they would, to overcome them by the same dogged courage and perseverance. Doubtless, in the struggle much is in favour of the high-born and the noble, but the elements of success are alike in both cases; external circumstances possessing not always the advantages imputed to them, the race here as in many other things not always being to the swift nor the battle to the strong. I make these observations at this time not without a motive. It is the last time which from this chair I shall have an opportunity of giving a word of advice to those who I am sure require it most, and for whom my sympathies are always most strongly excited—namely, those who are but beginning the struggle, or who are engaged, as it were, as yet in buckling on their armour. I may take it for granted, I think, that there is not a young man hearing me to-night who has not fixed a standard—be it high, or be it low—which he hopes to attain, and to which it may be even now he is striving to aspire. Well! I hope in every case it has been fixed high—the higher the better—and that he will ever keep it before his eyes with this assurance, that there is no path which other men have trodden, but in which if he choose he may not also follow; no standard reached by others which may not likewise be his own. If he could only make this thought his own, and let it penetrate all his actions and all his life, there is no height to which he could not reach, no difficulty which he could not overcome. And now, gentlemen, the last duty which I have to perform to-night is to thank you all for the kind indulgence and support which you have accorded me during the session in the various duties of the chair. It was not without many misgivings of shortcoming that I consented to take the chair, and though, on looking back over the work of the session, I am conscious of failures in many respects, I hope you will overlook them in the assurance that I have at least tried in every case to give you my best intention and my best effort."

Mr. Mackay proposed a very special vote of thanks to the retiring President, for the able and successful manner in which he had fulfilled the duties of the chair. On all occasions he had shown a deep interest in the affairs of the Society, and was always ready to render any assistance in his power to further the real business of the association. Mr. Mackay concluded his remarks by expressing the hope, that if requested, Mr. Gilmour would not object to occupying his present position for some time longer.

The Secretary then announced the arrangements for the summer classes on botany, materia medica, and chemistry.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The eighth meeting of this Association for the present session was held in the Council Room of the Church Institute, on Wednesday evening, February 24th. The President, Mr. F. Reynolds in the chair. After the preliminary business had been transacted,

Mr. Fairley, F.C.S., the Borough Analyst, read a paper on "Oxygen and its Compounds with Original Experiments." Many of the original experiments created a considerable amount of interest.

On the motion of Mr. Abbott, seconded by Mr. Longley, the usual vote of thanks was passed to Mr. Fairley.

The ninth meeting was held in the Science Lecture Room of the Mechanics' Institution, on Wednesday evening, March 10th. The President, Mr. F. Reynolds, in the chair.

A lecture on the "Chemistry of Carbon," was delivered by Mr. George Ward, F.C.S. The lecturer in commencing referred to the various modifications of carbon, and gave a brief description of the physical and chemical properties of each. The compounds of carbon with oxygen were then noticed and the chief properties of the monoxide and dioxide well illustrated by highly successful experiments. The preparation and properties of marsh gas and olefiant gas were next briefly noticed. Carbon was shown to be the essential element in that division of science described as organic chemistry—the supposed constitution of some organic compounds including alcohol, aldehyde, acetic acid, and ether, was clearly demonstrated by the use of glyptic formula, the tetrad functions of the carbon atoms in all these compounds being illustrated. The lecturer concluded by referring to the similar tetrad function of the element silicon, and the existence of compounds in the silicon series which were chemically quite analogous to the corresponding carbon compounds, enumerating the silicon chloroform and other substances as instances of the close analogy between the two series.

A vote of thanks to Mr. Ward for his very able lecture was, on the proposal of Mr. Childe, seconded by Mr. E. O. Brown, carried unanimously.

The tenth meeting was held on Wednesday evening, March 24, in one of the lecture rooms of the Yorkshire College of Science, for the convenience of the lecturer, A. W. Rücker, Esq., Professor of Physics in that College, who occupied the evening. "Some Physical Properties of Gases," the subject of his lecture, was handled in a masterly manner from the most recent stand point of scientific research.

The lecturer, after explaining the general principles of the molecular theory of the constitution of bodies, showed some experiments to prove that the motions of the molecules produce the phenomena of heat, and then passed on to a fuller account of the explanations which have been given on mechanical principles of some of the simpler thermal and physical properties of gases.

The pressure of gases and the production of heat by compression were explained by the aid of experiments, and diagrams were exhibited illustrating the changes in their velocities and directions of motion produced by the "encounter" of two of the constituent molecules of a gas; and an explanation having been given of the rapid equalization of pressure on all sides of the containing vessel when its equilibrium has been momentarily disturbed, the lecture concluded with a short account of the applications of the molecular theory to the phenomena of conduction and diffusion in gases.

The Chairman, Mr. F. Reynolds, having expressed the pleasure with which he had listened to the lecture and remarked upon the slightly increased attendance, called for a vote of thanks to the Professor, which was accorded by acclamation.

The eleventh and last ordinary meeting of the present session was held in the library, on Wednesday evening, April 14, the chair, as usual, being occupied by the President, Mr. F. Reynolds.

Mr. Edwin Yewdall delivered an address to students entitled "How shall I pass my Examination." He strongly advised them to rise early, and methodically divide their leisure hours for study. He then passed in review the various subjects comprised in the pharmaceutical examinations, offering a few practical suggestions on the study of each, and specially alluded to the value of microscopical investigations. A cordial vote of thanks was passed to Mr. Yewdall at the conclusion of his address.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The second monthly meeting of this Association for the present session was held at the rooms, Tudor Place, on the evening of Wednesday, the 14th inst., Mr. Maleham, the President, in the chair. The minutes of the previous meeting having been confirmed, the President said the business of the evening would be a debate on milk of sulphur. Mr. Ellinor, M.P.S., would open the discussion in the affirmative "That Lac Sulphuris is Sulphur Præcipitatum," and Mr. Ward, F.C.S., would be the leader in the negative.

Mr. Ellinor said—The question I have undertaken to defend is that lac sulphuris and sulphur præcipitatum, pharmacopœially, are simply different names for the same preparation, and not, as some allege, the names of different preparations. I feel a pleasure in defending this question, and hope that all present will take part in the discussion, and that whatever may be said will be taken in good part, it being understood that no personal feeling will be allowed to prevent a free discussion of the true facts. I purpose dealing first with the facts relating to this subject, and to leave the opinions for the after consideration. I will now introduce the historical facts.

"Lac Sulphuris Quercetani; Quercitan's Milk of Sulphur. ℞ Flowers of sulphur, ℥vj, sal regale, ℥xviij. Put so much water to the salt as will dissolve it, and over-top it six inches; put all into a wide mouthed glass in sand, so large that it may not be much above half full; boyl to dissolve the flowers, stirring them with a wooden spatula till the solution is red, filter whilst hot, and with sharp wine or spirit of vinegar, precipitate the milk, which edulcorate with water and dry."

"Lac Sulphuris Clossæi, Milk of Sulphur of Clossæus. Take powder of sulphur p. j, quick-lime p. ij; boyl them in an iron kettle in a pretty large quantity of water till it is red as blood; whilst hot, strain it; then, being cold, precipitate with hot piss; decant the humidity, and sweeten the precipitate by washing it ten or twelve times in hot water.

"From 'New London Dispensatory,' lib. iii, cap. xii, page 388–9, from the pen of Salmon, from his house at the *Blew* Balcony, by the ditch side, near *Holbourn* Bridge, London, March 10, 1684-5. Imprimatur Anton Saunders, Mart. 2, 1676."

I will now proceed to the P. L., 1721, of which I have here a copy for you to see, also I have here a copy of P. L., 1746.

Official name and process, P. L., 1721, page 137.

"Lac Sulphuris.—℞ Sulphuris partem unam; calcis vivæ vel salis tartari partes tres. Coque in aquæ fontanæ q.s.

ad solutionem sulphuris. Filtra calide; præcipita cum spiritu vitrioli; edulcora et sicca."

P. L., 1746, page 54. "Sulphur Præcipitatum.—℞ Flores sulphuris cum triplo calcis vivæ pondere coquantur in aqua ad solutionem sulphuris, et liquor per chartam coletur; deinde, spiritu vitrioli tenui addito, præcipitabitur pulvis, qui sæpius affusa aqua lavendus est, donec omnino insipidus fiat. Page 155 Index *nominum mutatorum* we find *nomina usitata* lac sulphuris, *nomina nova* sulphur præcipitatum.

P. L., 1787. Dr. Healde's translation, pages 111 and 112. "Sulphur Præcipitatum.—Take of sulphurated kali six ounces by weight, distilled water by weight one pound and a half, vitriolic acid diluted as much as may be sufficient; boil the sulphurated kali in the distilled water till dissolved, filter the liquor through paper, to which add the vitriolic acid; wash the precipitated powder by often pouring on water till it becomes insipid."

P. L., 1809. Dr. Healde's translation, page 106. "Sulphur Præcipitatum, P. L., 1787, P. L., 1745, Lac Sulphuris, 1720.—Take of sublimed sulphur a pound, fresh lime three pounds; boil the sulphur and lime together in water, then strain the solution through paper, and drop in as much muriatic acid as may be necessary to precipitate the sulphur; lastly, wash this by repeated affusions of water until it is tasteless."

P. B., 1867. The only change in this Pharmacopœia and P. L., 1809, is a nominal one, the name of the acid in P. L, 1809, being muriatic acid, and in the P. B., hydrochloric.

Pharmacopœial changes of name in hydrochloric acid—spiritus salis, P. L., 1721; spiritus salis marini Glauberi, P. L., 1746; acid. muriatic., P. L., 1788, 1809, 1824; acid. hydrochloric., P. L., 1836, 1851; P. B., 1864, 1867.

These extracts from the authorized Pharmacopœias and recognized translations of the same sufficiently demonstrate—

1. That *lac sulphuris*, milk of sulphur, was a Pharmacopœial name, 1721.
2. That lac sulphuris was nominally changed to sulphur præcipitatum *officially*, the process and articles used being identical, salt of tartar being omitted; and at page 155 Index nominum mutatorum, we find nomina usitata lac sulphuris, nomina nova *sulphur præcipitatum*, P. L., 1746.
3. That sulphurated kali was used instead of lime or salt tartar, P. L., 1787.
4. That lime and sulphur were again used precisely as before directed, and that muriatic acid was used for precipitating the sulphur, P. L., 1809.
5. That muriatic acid is now called hydrochloric acid no enlightened chemist and druggist will deny.
6. That the name sulphur præcipitatum has been retained in each succeeding Pharmacopœia since 1746 to 1867.
7. That the process has remained the same since P. L., 1809.
8. That the name sulphur præcipitatum superseded the name lac sulphuris before the process was changed.
9. That the name and process were both changed at the same time is not a fact, though it has been frequently asserted.
10. That it was the object of the compilers of the Pharmacopœias, prior to 1809, to get the sulphur in a pure state from the changes in the articles used in the process.
11. That washing the product of each Pharmacopœia was always directed, and never omitted.
12. That Clossæus' milk of sulphur would require a little washing, and that the process of making hot the urine might perhaps be pleasing to some, but such a mode of precipitating would require much washing.

To these I may add the following additional facts:—

1. That the greater part, if not the whole of the contaminated milk of sulphur sold is a bye product, and usually made at naphtha and benzol works from the gas tar products.
2. That it is illegal and very immoral to sell a bye product for a Pharmacopœia medicine, knowing the same to be contaminated with an article (sulphate of lime) which is so stable and difficult to dissolve or decompose that it must be hurtful to the human stomach when taken as a medicine.
3. That chemical manufacturers have to pay from 6*d.* to 1*s.* per ton for carting away sulphate of lime as rubbish.
4. That from 1, 2 and 3, we can easily understand the reason many wholesale houses push the sale of contaminated milk of sulphur.
5. That the label suggested by the legal advisers of Messrs. Hirst and Co., of Leeds—"Lac Sulphuris, Milk of Sulphur, not Precipitated Sulphur"—is simply a contradiction of a fact.
6. That I have had obtained for me on good authority information from manufacturers of contaminated lac sulphuris that it is nearly always obtained as a bye product, and *very* seldom made direct.
7. That Muspratt, in his 'Chemistry,' says manufacturers are guilty of substituting sulphuric for hydrochloric acid in making sulph. præcip. Attfield, and a number of others, write similar facts.
8. That such substitution (as in 7) increases the yield, if the sulphate of lime be not washed out.
9. That friends of contamination may beware "their sins will find them out." And I have great pleasure in producing for your examination the original Pharmacopœias from which I have quoted.
10. That by these remarks I prove the one great fact that lac sulphuris is not only superseded by sulphur præcipitatum, but that sulphur præcipitatum is lac sulphuris, and lac sulphuris is sulphur præcipitatum Pharmacopœially, officially, and legally.

Mr. Ward, in the negative, maintained that the arguments advanced by Mr. Ellinor were faulty in this respect, that he took the Pharmacopœial name and process of 1721, and assumed that they were synonymous with the preparation in the present British Pharmacopœia, whereas he denied that was so, and asserted that lac sulphuris of 1721 was one preparation, and the sulphur præcipitatum of the British Pharmacopœia was another. In support of his assertion he quoted the remarks made by several learned gentlemen, when the same subject was discussed in London. In elucidating his subject he had recourse to some amusing illustrations, and was supported by Messrs. Cocking, Doble, and Bradwall, Mr. Ellinor being supported by Messrs. Preston, Cubley, and Learoyd. After a very interesting and animated discussion, Mr. Ellinor replied to the general remarks. After which the opinion of the members present was taken, when the President announced that Mr. Ward had the majority of votes. A vote of thanks having been passed to the Pharmaceutical Conference for the 'Year-Book of Pharmacy,' a very agreeable meeting was concluded.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

An ordinary meeting of this Association was held on Wednesday evening, April 14th, Mr. W. Scott Brown, President, in the chair.

Mr. L. Siebold delivered the sixth lecture of his special course on "The Detection of Adulterations in Common Articles of Food and Drink." He stated that he had lately given his attention to a process for the estimation of foreign fats in butter, published by Mr. A. Angell and Mr. O. Hehner, and as the results he had obtained were exact enough for all practical purposes, he had much pleasure in recommending this process, the main features of which were the following:—Pure butter fat contains 85·8 (85·4 to 86·2) per cent. of insoluble and non-volatile fatty acids, whilst other fats, such as can be used for the adulteration of butter, contain 95·5 (95 to 96 per cent.), thus showing a difference of 9·7 per cent. A weighed quantity (about 3 grains) of the butter to be tested should be saponified with solution of KHO, the perfectly clear soap decomposed by dilute HCl, the separated fatty acids liquefied by heat, then collected on a moist filter, washed with boiling water, dried at 100° C., and weighed. Each per cent. found above 85·8 would indicate 10·36 per cent. of foreign fat in the fatty portion of the butter. Full particulars of this process would be found in the authors' pamphlet, which also contained an improved method for the determination of the fusing point of butter fat.

Cocoa.—As cocoa nibs contain about 50 per cent. of fat and about 3·4 (2·5 to 4·3) per cent. of mineral matter, the determination of the ash and of the fat, and the relation between the two results, would give an idea of the percentage of cocoa nibs contained in a sample of chocolate or other preparation of cocoa. Wanklyn recommends the cold aqueous extraction of the sample of mixed cocoa under examination, and the subsequent incineration of the dry extract. He found that good cocoa nibs yield 8·92 per cent. of dry extract, consisting of 6·76 per cent. of organic and 2 16 per cent. of mineral matter. The determination of the dry aqueous extract and of its ash would therefore throw additional light on the quantity of cocoa nibs present in the preparation. An adulteration with chicory might be detected by the deep colour which this substance imparts to cold water, as a cold aqueous infusion of pure cocoa is very pale in colour.

Mustard.—The lecturer stated that, as the fixed oil both in the white and the brown mustard amounted on an average to 36·5 per cent., the limits of variation being 34 and 37 per cent., the estimation of this oil by means of benzol or ether would indicate the presence or absence of adulterants. Wheat flour and other starchy farinas might be easily detected by iodine in the aqueous infusion of the mustard. For the detection of turmeric, a sample of the mustard should be treated with alcohol, filtered, and the filtrate mixed with solution of borax, which in the presence of turmeric would produce a red coloration. A more delicate and reliable mode of testing consisted in the immersion of a strip of filtering paper in the alcoholic filtrate during its evaporation on a water-bath, and its subsequent immersion in a strong aqueous solution of boracic acid. The paper after drying would then show a distinct red colour. Plaster of paris and other mineral adulterants might be easily detected by incineration, as genuine mustard never left more than 5 per cent. of ash. The presence of cayenne pepper could be recognized by the burning taste of the extract left on evaporation of an alcoholic tincture of the mustard. The addition of white mustard to brown mustard flour would cause a diminution of the volatile oil obtained by distillation; a genuine brown mustard should yield 1 per cent. of volatile oil.

Pickles and Vinegar.—Pickles should be tested for copper by incineration, and an examination of the ash according to the rules of qualitative analysis. The testing of vinegar had been described by the lecturer at one of the previous meetings. Since then he had noticed a new and thoroughly practical method for the detection of free mineral acids in vinegar, published by M. Strohl in the *Journal de Pharmacie et de Chimie.** It was based on the insolubility of calcium oxalate in dilute acetic acid, and its solubility in mineral acids. He, the lecturer, recommended the following mode of applying the test:—Two ounces of vinegar should be mixed with 1 fluid drachm of a saturated solution of calcium sulphate, and 25 drops of the ordinary test solution of ammonium oxalate. If the mixture appeared clear after a few minutes, mineral acids were present; if it was cloudy, they were absent, or amounted to less than 1 in 1000.

A few remarks on the detection of adulterations in pepper concluded the lecture.

* See *Pharmaceutical Journal*, October 3, 1874, p. 269.

The Chairman, in moving a vote of thanks to Mr. Siebold for his most interesting and instructive course of lectures, said the Association had been placed under great obligation to Mr. Siebold for having rendered such valuable services gratuitously throughout the session. The lectures had been a source of much gratification and information, and he sincerely regretted that they had now come to an end. It was unnecessary for him to repeat what Mr. Siebold and every one in the room knew to be his opinion as to the ability of the lecturer.

Mr. Benger said it gave him the greatest pleasure to second the resolution. When they remembered the length of time and the amount of thought and care bestowed by Mr. Siebold on these lectures—often when suffering from illness and worried by other pressing engagements—they must all feel very deeply indebted to him indeed. In Mr. Siebold's presence he could not, in good taste, say all he would like to say, but he might be allowed to congratulate the associates on their good fortune in having such a man to conduct the chemistry and materia medica classes. In him the scientific chemist, the practical pharmacist, and the experienced teacher were combined, and this combination exactly met the requirements of their school. Some of them might possibly remember the instructive story of a certain American cow that was accidentally, or ignorantly, fed on pine shavings instead of hay, and the mistake was only discovered by the milk-maid, who found that the cow gave turpentine instead of milk. An analogous discovery was too often made in the examination room of the Pharmaceutical Society, but he was convinced that Mr. Siebold's pupils would never be found in this abnormal condition.

The resolution having been carried with acclamation, Mr. Siebold briefly replied and the meeting terminated.

WOLVERHAMPTON CHEMISTS AND DRUGGISTS' ASSOCIATION.

The last monthly meeting of the present session in connection with the above Association was held on the 15th inst. at the Agricultural Hall. Mr. Fleeming, President, was in the chair. The minutes of the last meeting having been received and adopted, Mr. Barrett, the Junior Secretary, announced donations of books, etc., to the library and museum, of the *Pharmaceutical Journals*, the 'Calendar for 1875,' and the 'Library Catalogue' from the Pharmaceutical Society; a number of prescriptions, from Mr. Joseph Ince; 'Lessons in Elementary Chemistry,' and 'A Course of Practical Chemistry,' from Professor H. E. Roscoe; 'Adulterations Detected,' from Dr. Arthur Hill Hassall; 'Materia Medica and Therapeutics,' from Dr. C. D. F. Phillips, M.D., F.R.C.S.; 500 library labels, from Mr. Henry Silverlock; 'Antiseptics,' from Dr. A. E. Sansome; 'Dict,' 'Winter Cough,' and 'Reports on the Progress of Medicine in Different Parts of the World,' from Dr. Horace Dobell; Mr. John Clarkson Major, one guinea.

The hearty thanks of the Association were accorded to the donors.

The Senior Secretary (Mr. Brevitt) then read the report, which opened by stating that in accordance with a desire expressed at the last meeting, the secretaries had forwarded copies of two resolutions embodying the opinions of the members with respect to the Adulteration of Food Bill to the borough and county members, and that their communications had been very courteously acknowledged, and the secretaries had great pleasure in announcing that some alterations had already been made in the bill, which to some extent met the wishes of the members. The report continued as follows:—

"At a Council meeting held this evening, it has been determined to offer two prizes for competition to the students attending the classes on materia medica and botany. The examination papers will be drawn up by Mr. Stokes-Dewson, who will also report upon the respective merits of the answers to the Council, who will award the prizes.

"Our members will hear with regret of the death of Daniel Hanbury, a friend to this Association, as he was to all societies having for their object the education and advancement of the followers of Mother Pharmacy. His book and the cordial letter of congratulation he wrote on the establishment of our Association will, we are sure, be long treasured by our members and students as a memento of him. His loss will be felt by all English and continental pharmaceutists.

"You are probably aware that this is the last meeting of the session. The next monthly meeting will be held on October 14th, when an address to the students will be delivered, and a full programme issued for the session. It is premature to surmise what programme the Council may arrange, but, as the society has been so successfully commenced, it is, perhaps, not too much to expect:—(1) that a full course of lectures (occupying six months) will be delivered on all the subjects required for the Preliminary, Modified, Minor, and Major examinations of the Pharmaceutical Society; (2) that suitable rooms will be engaged for the sole use of the Association; (3) that the proposed library and museum, towards which much help has been promised and given, will be in full working order; (4) and as some help will doubtless be given by the Pharmaceutical Society, we may confidently hope that our Association will be able to offer greater advantages to members and associates than it has been able yet to do, owing to its somewhat hurried establishment. You will be glad to hear that our library is steadily increasing in extent. Your secretaries have taken care to bring the work of your Association before the authors of works on pharmacy and the allied sciences, and many kind letters and promises of help have been received. Our monthly meetings will, it is hoped, during the new session, assume a more important character, and the Council respectfully urge members and associates to prepare during the leisure summer months a subject to bring forward at these evening meetings. Several gentlemen have already promised papers,—amongst others, Mr. E. W. T. Jones, F.C.S., Mr. W. L. Scott, F.C.S., Mr. J. G. Morris, F.C.S., Mr. Brevitt, etc. During the summer months the associates will not be forgotten. It is proposed by the Council that a sort of lending library should be formed with the books we have already obtained, and that the cases of materia medica specimens and the herbarium should, under certain circumstances, be also lent to the students. The room in Darlington Street will be, as heretofore, open to students on Friday nights. It is hoped that some arrangements may be made with volunteer teachers for the holding of occasional classes during the summer months. The secretaries will be happy to receive the names of gentlemen thus volunteering their services. Should any business require the attention of the Council, or of the members of the Association, the secretaries have been empowered to call a special meeting of the Council or of the members. Although we have occasion to be pleased with the great success which has attended the establishment of the Association, we may confidently hope to receive greater encouragement in the session of 1875-6."

The Chairman said they might congratulate themselves upon the above very elaborate and able report, and might feel proud of their indefatigable secretaries, and he was sure they had all much pleasure in hearing and receiving the report.

Among the objects of interest exhibited, were Westphal's apparatus for ascertaining the density of fluids, by Mr. W. L. Scott, F.C.S., and Mr. Hancock's patent drug-mixing machine, by the inventor.

Mr. Stokes-Dewson then gave an address on drug adulterants. Amongst other drugs he mentioned senna, ipecacuanha, Opium, etc., and showed specimens of various spurious drugs, and described their appearance and effects as compared with the articles for which they were sometimes substituted. This paper gave rise to a lengthy discussion, in which several of the members took part.

Parliamentary and Law Proceedings.

Poisoning by Strychnine given in Mistake for Santonin.

Charge of Culpable Homicide against a Doctor's Assistant.

At the Glasgow Spring Circuit Court, on Thursday, April 22, Alexander Jamieson was placed at the bar on a charge of culpable homicide, in so far as on the 9th of March, while employed as an assistant in the dispensing of medicine and drugs in the shop of Dr. James Allan Smith, Springburn Road, Glasgow, he did give to John Parker a quantity of strychnine, and instructed him to administer it to a child, which Parker did, in the belief that the strychnine so supplied was a powder for destroying or expelling intestinal worms, and the child—Isabella Dott Pendrich Parker—who was between seven and eight years of age, immediately after taking it was seized with violent convulsions, and died from the effects of the powder.

The prisoner, a young man, pleaded not guilty, and was defended by Mr. M'Kechnie.

John Parker, engine-fitter, residing in Wellfield Place, Springburn, was the first witness called. He said—I am father of the deceased child. On the night of the 9th March the child was ailing from, as I thought, intestinal worms. A shopmate advised me to get a crystal powder. I went to Dr. Smith's shop and asked his assistant for "a dose of crystal powder for a girl about eight years of age." He brought out a "dusting" powder, and I told him that was not what I wanted, but a crystal powder for a child complaining of worms. After that he said, "That's a queer dose for a child eight years of age," and he then went to a press and took a bottle from a shelf without looking at it. There were other bottles on the shelf. He gave me some of the contents of the bottle. He told me to give my child the powder at night, when she had an empty stomach. He advised me to give her some senna next morning. The powder was not labelled. I gave the child the powder between nine and ten o'clock. I tasted it myself; it had a strong bitter taste, I think, but I was smoking at the time. The child, about four minutes after taking the powder, screamed violently. My wife called my attention to the screaming, and I went to the bedside. I set my daughter up on the bed, but she said, "Daddie, I can't stand." I saw at once there was something wrong. I sent for Dr. Smith, who gave her some mustard and water, and went to the shop to fetch something else. By the time he returned the child was dead. After the death I met the doctor coming up the stairs. He showed me a piece of paper, and said, "Is that anything like it?" I said, "I don't know." I thought he meant whether the paper was like that in which was the crystal powder. When the powder was given to the child I threw the paper in the fender, but when I saw that something was wrong I took it up again, and he had got the paper before he went to the shop. On his return he asked me if I could point out the bottle in the shop out of which the powder was taken. I went down to the shop and did so. The bottle now shown me is like that out of which the prisoner took the powder to give to me. When I was shown the crystal powder by Dr. Smith's sister, I saw it was different from that which I had received. The label on the bottle shown to me is the same as that which was on the bottle which I pointed out and handed to the doctor. When Dr. Smith saw the bottle he said, "What'n a' the world has he been thinkin' about?" He told me the best thing I could do was to go down to Jamieson's house and fetch him up. That was close upon twelve o'clock at night. I went and got Jamieson, and he went with me to Dr. Smith's house. In answer to Dr. Smith, Jamieson said the crystal powder was called santonin. The doctor afterwards asked Jamieson if he had sold me a powder, but I did not hear the answer. They all afterwards went to the shop, and the prisoner declared that the santonin was the powder he had given me. I declared it was not it, for there was a great difference in the powders. I tasted the powders, and the santonin had, as I thought, a sweetish taste. I went to the press and fetched the bottle out of which he took the powder for me. I tasted it and found it was bitter. After thinking a little the young man said, "Doctor, I give in." The doctor and the prisoner talked together. He asked me to meet him and Jamieson next morning so as to go before the Sheriff. I went home, but after that I went and told the police, and the prisoner was apprehended.

Cross-examined by Mr. M'Kechnie: I did not see the bottle when the prisoner was filling out the powder, as it was so small as to fill his hand. I think I should know the bottle again. (Shown the santonin bottle.) That's not it, the powder was not so fine. (Shown the strychnine bottle.) That's something like the powder that I got. I judged by the powder. I was able to pick out the bottle by the look of the powder and by the taste. I am not aware that at this time Jamieson knew that the child was dead.

Isabella Parker, wife of the preceding witness, corroborated the evidence of her husband. She said the girl was cramped all over after she took the powder. She gave the child some mustard and water according to the doctor's instructions, and soon after the girl died. The body was examined by Drs. Moore and Dunlop on the following Thursday.

Dr. Jas. Allan Smith deponed: The prisoner has been with me for about nine months as my assistant. I was aware Jamieson had been in the habit of dispensing medicines for some time previously. On the 9th of March, about ten o'clock at night, I was called to the house of Mrs. Parker, and I found there a child in violent convulsions. I thought first these were proceeding from some complaint, but on the second attack I saw at once it must have proceeded from poison. The whole body appeared to be in one spasm and bent back and the feet were inverted. I tried to make the child vomit, but was not successful. I went away to get some other medicine, when a messenger came and I hurried back, but found the child dead. When Parker went down with me to the shop he went to the press where the liquids were kept, and on being told that could not be the place he went to the other press and brought the bottle marked "santonin," and tasting it said that was not it. He looked again but could not find it. I took out about a score and laid them on the floor before him, and he picked out the strychnine. He opened the bottle and tasted it, saying that he recognized it by the taste. The bottle marked "poison" is the one. Witness then detailed the conversation between Jamieson and himself as to the powder. He told prisoner that the child had died, and the parents thought they must have got poison. Jamieson, after looking at both bottles, came to the conclusion that he must have made a mistake.

Cross-examined by Mr. M'Kechnie: I always found Jamieson careful in dispensing, and I have the highest opinion of his character. I am aware that he became a licentiate of the College of Surgeons in Edinburgh in January last. Medicines in daily use in my practice were not kept beside the poisons. When Jamieson was absent my sister took his place. The shop was shut at mealtimes.

Dr. Jas. Dunlop deponed that on the 11th March he made a *post-mortem* examination, along with Dr. Moore, of the body of the deceased girl. He read the report, which stated that he and Dr. Moore were of opinion that the appearances presented by the body of the deceased were compatible with those of poisoning by strychnine. He removed the stomach and its contents and a portion of the liver, sealed them up, and handed them over to the sheriff-officer.

By Lord Deas: There was no other cause of death, and strychnine was sufficient to cause death.

Dr. Samuel Johnston Moore corroborated the evidence of Dr. Dunlop as to the *post-mortem* examination.

By Lord Deas: We saw no cause for death, though all the appearances were compatible with poisoning from strychnine, and hence the necessity for analysis.

Dr. Maclagan, Edinburgh, deponed that he made an analysis of the two jars sent him. He made a report, which stated that in the stomach he found seven-tenths of a grain of strychnine; and in the liver there was also strychnine. The whole analysis was sufficient to show that the child must have swallowed a considerable quantity of that poison—sufficient to cause death. The samples of santonin and strychnine now shown him were very distinct the one from the other.

Cross-examined by Mr. M'Kechnie: There are far more than fifty active poisons. Almost all the drugs that are in use are poisons. It is very difficult to say what is not a poison. But there are not fifty poisons of the same activity as strychnine in ordinary use.

Lord Deas: If there are, I hope you won't tell.

The declaration of the prisoner stated that he believed he must have given strychnine to John Parker instead of santonin.

This closed the evidence for the prosecution.

For the defence,

Dr. Reid, Dumbarton Road, deponed that Jamieson was in his dispensary rather more than three years. He was careful and attentive during the time he was with him. He was aware of one case where the overweight of a powder out of one bottle was put on the counter and afterwards returned into the wrong bottle.

Dr. Macleod, Professor of Surgery in the University of Glasgow, deponed that Jamieson was a very careful student while under him for two years.

Dr. Cowan, Professor of Materia Medica in the University of Glasgow, deponed that Jamieson took second class honours in witness's class.

This closed the evidence.

The Advocate-Depute addressed the jury, and craved a verdict of guilty.

Mr. M'Kechnie, for the prisoner, said that it was not at all likely that a man practised in the dispensing of medicines would take out a bottle labelled "Strychnine, poison" for one labelled "Santonin," and he suggested whether it was not possible that the strychnine was in the bottle labelled "Santonin." The Crown had not proved whether the powder in the santonin bottle was pure, as it might have happened that the one powder got mixed with the other. Should such have been the case, was the prisoner to be held resposible for that? Because the Crown had not proved that the santonin powder was pure, he asked the jury to consider the present case not proven.

Lord Deas then summed up.

The jury retired at a quarter-past seven, and after an absence of ten minutes, they returned into court and gave the following verdict:—The jury, by a majority, find the panel guilty of manslaughter, but unanimously recommend him to the mercy of the Court.

Lord Deas, in passing sentence, said: It is very unfortunate that you stand in the position you now do, but it would be more unfortunate if the Court were to do anything that would indicate to persons in your position—for there is a numerous class of persons employed in druggists' and chemists' shops—that an offence of this kind, causing the death of a fellow-creature, was a light one. That is not so at all. It is a very serious offence. In your case it is very difficult to see any mitigating circumstances. Not only were the two powders different, but if you had only looked at the outside of the bottles you might have seen the difference. We are desirous to give effect to the recommendation of the jury, and will give effect to it, but after full consideration we cannot make the punishment merely nominal. It is impossible to make it less, if it is to have its proper effect in deterring other people, than imprisonment for three months.—*Glasgow Herald.*

Alleged Adulteration of Coffee.—Disputed Analysis.

At the Brackley Police Court, on April 14th, Mr. George Kennedy, grocer, of Grimsbury, was charged with selling a quarter of a pound of ground coffee, which had been adulterated. Defendant was represented by Mr. Crosby. Inspector Botterill gave evidence as to the purchase of the coffee. On the 1st inst. he received a certificate from Mr. Young, to whom he had submitted the coffee for analysis, as follows :—"Percentage of ash, 3·68 per cent. ; specific gravity of 10 per cent. decoction, 1·0068, equal to 16 per cent. soluble matter ; farina or starch, none ; sugar or saccharine ingredients, traces. Microscopic appearance most unsatisfactory. Remarks, adulterated with at least 20 per cent. of roasted acorns." Mr. Crosby said the coffee had been supplied to the defendant by Mr. R. Stevens, grocer, Banbury, who had instructed Mr. Beesley to analyse the sample left with the defendant. Mr. Thomas Beesley, analytical chemist, Banbury, said he had examined the coffee microscopically and chemically, and there was no adulteration present whatever. The case was adjourned, the coffee to be submitted to a third analyst.

The case was brought forward again at the Middleton Cheney Petty Sessions, on Monday, April 26th, before R. A. Cartwright, Esq., chairman, and Colonel Cartwright.

Mr. Crosby said that he appeared for George Kennedy, grocer, Grimsbury, and John Merivale, grocer, Middleton Cheney, who were summoned at the last Brackley meeting for selling adulterated coffee, and whose cases had been adjourned.

The Chairman said that George Kennedy was summoned to Brackley for selling adulterated coffee. Mr. Beesley's evidence having been taken, to the effect that the coffee was pure, it was agreed to submit the sample to Dr. Letheby, for analysis, and Dr. Letheby had reported that the coffee was perfectly pure. Dr. Letheby's certificate was as follows :—"In the matter of a sample of ground coffee from Brackley—I hereby certify I have carefully analysed chemically and microscopically a sample of ground coffee delivered to me on Saturday last, the 17th inst., by Charles Botterill, Inspector of Food, Brackley, and I find it to be pure and unadulterated coffee, in a rather finely ground condition. The sample was contained in a small rectangular canister, enclosed in brown paper, and securely tied and sealed with red wax, with the seal, Young, chemist and analyst, Leicester, and marked No. 35, 9 February, 1875, upon a printed label of Joseph Young, pharmaceutical and analytical chemist, Leicester. The wrapper, with seal unbroken, is enclosed—Henry Letheby, M.B., M.A., Professor of Chemistry in the College of London Hospital, and late Medical Officer of Health and Food Analyst for the City of London, 17, Sussex Place, Regent's Park, London, April 19, 1875." The Chairman continued, and said the Bench thought proper to dismiss the case. Mr. Crosby might send in the costs incurred in the case to Messrs. Weston and Barnes, and they would consider whether they should be paid.

Mr. Crosby : I may take it that my client leaves the court without a stain upon his character.

The Chairman : Having taken the opinion of such an eminent authority as Dr. Letheby, we say that Kennedy is perfectly free from the charge brought against him.

Mr. Crosby : Will you allow the costs in Merivale's case ?

The Chairman : We did not go into that case.

Mr. Crosby : But we did.

Mr. Barnes : Mr. Crosby will understand that there is no order as to costs to-day. If an order is made it will have to be taxed.

Mr. Crosby : There was a different certificate in Merivale's case, and Mr. Beesley made an analysis of Merivale's coffee.

The Chairman : We did not order the analysis.

Mr. Crosby : We did, so as to meet the charge.

Mr. Barnes : If you send in particulars, we will see if we can get the costs allowed.

The Chairman : All we say is, send in your costs in the first case. We dismiss the case against Kennedy, and withdraw the summons in the other.

The following is the report of Mr. Beesley, F.C.S., on the coffee in question :—

"Remarks on the certificate of Mr. Joseph Young, analyst for the county of Northampton, of his examination of Kennedy's coffee.

"(1) 'Ash—3·68 per cent.'

"I found 3·80 per cent., which is almost exactly that found by other chemists in ordinary "plantation coffee ;" but I do not attach much importance to the discrepancy, as the percentage varies somewhat with the heat applied.

"(2) 'Specific gravity of 10 per cent. decoction, 1006·8, equal to 16 per cent. of soluble matter.'

"I found the specific gravity of the decoction to be 1008·2, which was found by actual experiment to correspond to 20·1 per cent. of "soluble matter." Graham, Stenhouse, and Campbell in their "Chemical Report on the Mode of Detecting Vegetable Substances mixed with Coffee for the Purpose of Adulteration" (*Journal of the Chemical Society*, vol. 9, p. 39, 1857) give 1008·7 for a similar quality of coffee.

"The specific gravity of a decoction of roasted acorns is 1007·3—higher than the analyst's figures for the sample of Kennedy's coffee.

"(3) 'Farina or starch none.'

"This is a very important admission. Roasted coffee contains no starch, whilst roasted acorns contain abundance of it, which may be easily detected in the decolorized and cooled decoction by the use of iodine. This statement alone is sufficient to invalidate the analyst's conclusion.

"(4) 'Sugar or saccharine ingredients—traces.'

"Coffee, when roasted, hardly ever contains more than 1 per cent. of sugar. Roasted acorns contain 2·7 per cent. (Graham, Stenhouse, and Campbell and others). This is another confirmation of the genuineness of the sample upon which the analyst operated.

"(5) 'Microscopic appearances. — Most unsatisfactory.'

"The contrary of this is strictly true, as the coffee differs in no particulars from a sample of genuine coffee, which shows a collection of brownish-yellow angular cells containing transparent globules of oil, with a few large elongated cells with oblique markings, belonging to the testa or investing membrane. No starch granules occur ; but such granules are the chief ingredients of roasted acorns, and are seen in great numbers in a microscopic preparation of this substance, enlarged and agglutinated by heat into masses of the shape of a mulberry. These become coloured blue by the application of a little tincture of iodine. This test is so delicate that a thousandth part of acorns might be detected mixed with coffee. Not a trace is to be found in Kennedy's coffee, as indeed is admitted in a former part of the certificate.

"(6) 'Remarks—Adulterated with at least 20 per cent. of roasted acorns. Such admixture is prejudicial to health, and by reason of its powerful astringent properties is calculated to lead to injurious results.'

"I am not concerned to defend the use of roasted acorns, particularly as an adulterant ; but it may be remarked that in former times acorns supplied a chief article of food to the poorer classes in most European countries ; and that there is no evidence of the injurious effects of roasted acorns, known on the Continent as "acorn coffee," when used as a coffee substitute. It is probably no more, perhaps even less, objectionable than chicory."

Mr. Beesley has analysed a sample of coffee sent to him from Burton Latimer, near Kettering, in regard to which proceedings were being taken on Mr. Young's certificate.

His analysis was—Ash, 5 per cent.; specific gravity of decoction, 1008·6, equal to 21·4 per cent. of soluble matter; no starch; sugar traces; no appearance of adulteration, especially of acorns, under the microscope. We understand that the summons in this case has been withdrawn, and in all likelihood no further proceedings will be taken in the other cases which are pending. In the case at Daventry, where there was a conviction, an appeal has been made to the Quarter Sessions.

There was no explanation offered as to how the discrepancy in Mr. Young's analysis of Kennedy's coffee had been arrived at. It is said that the matter will be brought before Parliament through the Chamber of Trade.—*From the Grocer and the Banbury Guardian.*

Notes and Queries.

[430]. HORSLEY'S TEST FOR ALUM IN BREAD.—The tinct. of logwood should be made with 1 oz. of logwood and 1 pint of proof spirit, digested a week and filtered. The carbonate of ammonia solution, about 3 ozs. of the carbonate to a pint of water. I do not know whether the strength of either of these is the same as recommended by Mr. Horsley, but I find them to answer admirably. In examining a number of samples of bread, each piece should be put in a separate dish or beaker, with just sufficient of the dilute logwood and ammonia solution to cover them. (Equal parts logwood and solution, and 8 parts water.) Let them stay in the liquid five minutes, then drain and dry.—ENGLAND.

[436]. UNGUENTUM PAGENSTECHERI.—Dr. Anton von Waldheim, of Vienna, has kindly forwarded the following formula, in reply to the query of W.B.C.:—

℞. Hydrarg. Oxyd. Flav. . . grana quatuor.
Cold Cream. . . . . . drachmas duas.

We are also indebted for similar answers from G. F. (Vienna) and Mr. E. Hefford.

[438.] MICROSCOPIC EXAMINATION OF STARCHES.—Canada balsam is the best medium for mounting starches, and by using the polariscope the characteristic markings are very clearly defined, not rendered imperceptible as "Micro" supposes. A ¼ inch objective should be used with plenty of day light. I have found myself that the microscopic difference between Natal and Bermuda is but little, the size of the grains being the same; but the markings are brighter in the latter. A jelly made from an equal weight stands much longer from Bermuda than from Natal, but not sufficiently long to account for five times the price.—OCTAVIUS CORDER.

THE GLASGOW MEMORIAL.

Sir,—Permit me once more to trespass on your space with a few additional explanations regarding the Glasgow memorial.

It appears from the minutes of the Glasgow Chemists and Druggists' Association, that the memorial, as submitted to the meeting of the trade, at which about sixty persons were present, did not contain the preamble objecting to the mode of appointing examiners in Scotland especially.

This is so far satisfactory, and corroborates what I stated in my previous letter. It would indeed have been difficult for any one having a spark of self-respect to retain an office to which, in the opinion of a large number of his brethren in trade, he had been "appointed by a mode unfair to the great body of qualified pharmaceutical chemists throughout the country, and detrimental in some respects to the interest of the young men who presented themselves from time to time for examination."

A committee of two or three members of council including myself, was appointed to superintend the memorial; no meeting of this committee, however, was ever called *ad hoc*, it being simply intimated on the ordinary notices that Memorial Committee was to meet fifteen minutes before the hour fixed for other business. A matter of such importance merited that, at least, one evening should have been allotted to discussion of its various clauses, instead of its being mixed up with price lists and other business.

At a meeting of our Council here yesterday, a motion made by me that the memorial be withdrawn had only three supporters out of eleven, the majority feeling themselves pledged to go on with it as it had been already presented, but all repudiated the insult to the examiners implied in the preamble.

As Messrs. Currie and Fairlie seem alone responsible for this preamble, it is for them to explain how they came to express themselves so as to be so thoroughly misunderstood. Mr. Fairlie adduces in support of his demand for frequent changes of examiners the case of two young men, who having failed twice in the Minor are now carrying on business on their own account under the protection of different surgeons, who are the nominal proprietors of their shops. These young men have assured Mr. Fairlie that they would not present themselves again before the same examiners, but that if there were a new board they might have courage to try once more.

I need scarcely point out the absurdity of this reason, or dilate on the advantages a candidate has in coming up more than once before the same examiners, advantages which themselves have formed a strong argument for frequent change in the *personnel* of examining boards.

I simply ask was it with a view to encourage or not to "estrange from the business" such men, that an attack was made on the mode of appointing examiners, especially in Scotland, ignoring the fact that the Council which nominates these examiners is elected by the suffrages of all the members of the Society in Scotland—that a demand was made for a board to sit in Glasgow, keeping out of sight the stronger claims and greater hardships of Aberdeen, a district which sends more candidates to Edinburgh than does the West of Scotland, and that the hitherto unavoidable necessity of having a large proportion of members, both of council and examining board, resident at the centre of action, has been attributed to selfishness and jealousy!

Peccavimus, peccavimus verumtamen miseremini nobis; there is some reason for a memorial, although the present one has erred. For my part I should be content if all this pother were to end in a return to the former system of crediting a candidate on his second examination with marks obtained in those departments in which he made a respectable appearance before.

As to the scarcity of assistants, that arises from the same causes which have been in operation according to my own observation for the past thirty years, and masters, examiners, and legislators would do well to bear in mind that druggists cannot be raised by conscription, and that if the trade is made too onerous or unremunerative the supply will fail entirely.

ALEX. KINNINMONT.

Sir,—In a previous letter I assumed that much of the discontent, at present manifesting itself in the west of Scotland, against the whole system of examinations, arose from an existing scarcity of assistants, which the druggists there in some way or another associated with, or directly imputed to the examinations. That this assumption was correct, is more than proved by the correspondence which has taken place in the Journal regarding this Glasgow memorial, and as the opinion that examinations and scarcity of assistants are cause and effect is not indigenous to the west of Scotland, and as moreover it is an opinion, which, if erroneous, is fraught with the most grave danger to the best interests of pharmacy, the present, I think, is not an unfitting time seriously to consider and review the whole subject. In doing so, I am aware that mere opinion, unsupported by data, is valuable only in so far as the individual has had the opportunity of extensive observation, and the ability to deduce therefrom sound and just conclusions, and it is therefore with no dogmatic spirit I wish to approach the subject, or seek to assert the extent of my observations, or the soundness of my opinions over all others, at least where these opinions are thus unsupported by facts. Granting then, in the meantime, that there is a scarcity of assistants, there is one point which it seems to me at the very outstart ought not only to be distinctly understood but demanded even as a *sine quâ non* to the consideration of the whole subject, namely, that although it can incontestably be proved that it is to the examinations a scarcity of assistants is more immediately imputable, it does not necessarily follow that therefore the examinations are to be condemned, or even held to be unwise or unjust in any degree whatever. Many conditions may obtain for example, apparently producing through the examinations a scarcity of assistants, and yet the examinations may have presumably nothing more to do with the scarcity than the reagent has to do with the presence of the poison which it detects. It discovers the poison to be there, it may even indicate to some extent through inference how it came there, but it does not itself produce it. In the same way, the examinations may discover that an inferior class of men are presenting themselves, but it does not produce this state of things, it only discovers it. The elements producing it may have been at work long before ever examinations existed, and the same state of things might have obtained at the present moment had they never existed. Not less important is another point closely allied to this which is too often forgotten or overlooked—namely, that although the examinations alone are producing this scarcity it does not necessarily prove that their standard should in any way be reduced, or that the exigencies of the case may not be met by means other than a reduction of the standard. The scarcity may simply be revealing the fact that the inducements held out for more or better men are disproportionate to the restrictions, or the learning required of them, without affecting in the least the entirely different question of the obligation of the Society as to these examinations, or the other questions as to the safety of the public or the requirements of Government. These last considerations, which are after all the only legitimate ones in regulating the standard, have too often been entirely overlooked, and the whole question prostituted into one of self interest or profit.

Keeping then these points in view I cannot but think that this question of the scarcity of assistants may be, and indeed for further reasons which I am about to consider ought to be settled without reference to the subject of examinations whatever; for apart from the possibility of this settling it without reference to them, I am firmly persuaded that they have had as yet (I will not speak as to what they may have in the future) little if anything to do with this scarcity.

In endeavouring to trace this scarcity to its true source it is necessary that I here for a moment resort to one of the principal channels from which the apprentices and, of course, assistants have been drawn in Scotland (I am speaking of Scotland entirely at present) in the past, and consider how far this channel is supplying them at present, or will continue to supply them for the future. It is a remarkable fact that in Scotland in the past the great majority of apprentices, especially in country towns—the great nurseries of our apprentices, have been drawn from the upper and even middle working-classes. The education which they received, generally a most liberal one for their station in life, under the excellent parochial system existing in Scotland, not only fitted them to a considerable degree for this position, but even inclined them to it as something higher and better than the mere round of manual labour which would probably otherwise have been their lot. This source might have continued sufficient until now, had not circumstances meanwhile somewhat altered the whole aspect of social matters. Within the last ten years, it is not too much to say that the whole aspect of affairs connected with the working classes has undergone an entire revolution. Not only are they receiving greater remuneration—it might be said in many cases double remuneration—for their labour, but their whole condition has been ameliorated. They have not only shorter hours of labour, but their very labour has to a great extent changed its nature, and is not now so degrading. In addition to this, manufactories have everywhere increased, and new industries have everywhere been opened up, demanding labour, intelligence, skill, education, and not only demanding them, but bribing them, if the expression may be allowed, with noble remuneration. I have in my mind at this moment, the condition of a sleepy little town (but the centre of a very large district), ten or twelve years ago, with only one large manufactory, at that time, in all its limits, employing in all only a few hundred hands. Since that time, one by one, its manufactories have increased, and new industries have sprung up, and now thousands are employed for every hundred formerly. It has literally swept the district of man, woman, and child, and so what was formerly a perfect hot-bed for apprentices is now converted into a modern Rama from which no fictitious sound of mourning and lamentation is now proceeding. This is by no means a fancy picture, or a solitary example. I could show the same operations going on less or more in every centre of labour. I could show how it is especially operating at the present moment in such centres as Glasgow under the very eyes of the memorialists: and what have they done to meet or remedy the evil? Let the correspondence which has appeared in the Journal about the remuneration, and the hours of labour, as well as this famous memorial, reply. I can well understand the bitterness with which some write, a bitterness which many more probably feel in silence when they think on what they are, and on what they might have been (and on what they now possibly can never be), had their lives only fallen to them in any other place than behind a Glagow druggist's counter, if these letters are a true indication, as I believe they are, of what the whole trade is there.

But not only have the circumstances which I have just indicated had the direct effect of limiting the supply of apprentices, and consequently of assistants, but they have had also an indirect, or what we may call a reflex action, but not less mischievous in its nature. Indeed it is much more mischievous and insidious because more difficulty to trace, and if we mistake not in it will be found the explanation of much of the outcry at present raised against examinations. This reflex action is shortly this, that this very scarcity is at the present time operating in producing altogether an inferior class of assistants. The very difficulty of getting them at all permitting no choice in the selecting, men are in consequence being drafted into the business who, neither by education or anything else, are fitted for the position. In this we have at once the explanation of the numbers who are rejected monthly at the examination, and to a great extent also of the unpopularity amongst a certain class of the examination itself. Never looking for a moment beyond the fact more immediately before their eyes of the percentage of rejections, never thinking that there may be circumstances beyond, which have operated in producing it, and waking at last to the, to them, terrible conviction that they will soon have left but one of two alternatives, no assistants, or proper remuneration with amelioration, it is not difficult to understand how examinations have become with them a species of war cry, or meetings and memorials a modified form of war dance.

With all these conditions operating so powerfully to prevent young men entering the business, it is not difficult to understand how they might also react on those who had already entered it by again withdrawing them, and thus produce another and equally fatal source of scarcity. In confirmation of this, I can give as the most powerful argument my own experience. Of all the assistants (upwards of a dozen, some of them having been many years at the business, none of them less than four or five, and all of them qualified by examination or other ways) who have passed through my own hands during the past eight or nine years, considerably more than one half at the present time have left the business for good. Comment on a fact such as this is, I think, unnecessary, and so I will let it speak for itself.

In drawing this series of letters to a close, I may be allowed to say that they never for a moment were intended either as an apology for, or vindication of the system of examinations as now adopted in London or Edinburgh, nor were they intended to champion the Scotch Board of Examiners. The latter can, and doubtless, when necessary, will speak for themselves, whilst the former in some points I do not approve, and have both by word and deed ere this tried to change. They have been prompted entirely by the wish to expose error and discover truth, and if they in any way succeed in this, either directly, or by drawing more attention to some of the points touched upon, it will be sufficient apology at once for inflicting them upon the public, and taking up so much of your valuable space.

SCOTUS.

P.S.—In reference to Mr. J. M. Fairlie's request that "Scotus" would send him his name, and he "might be induced to reply, etc.," "Scotus" has to say that there is no explanation which he can receive in private from Mr. Fairlie, which he may not as well receive in public. There has already been too much tortuous and underhand work in connection with this memorial for "Scotus" to be a party to any more, and he therefore calls upon Mr. Fairlie if he has any explanation whatever to give, to come forward openly and honestly and give it through the pages of the Journal in which he has been assailed. If they are matters of fact, which "Scotus" refers to, it can matter little whether Mr. Fairlie has his name or not, if they are not matters of fact, it is easy for Mr. Fairlie to deny them.

Sir,—As a number of druggists of my acquaintance cannot understand the meaning of that part of my letter to you on the 13th April treating on suggestion 2 of the Glasgow memorial, allow me to make the following explanation:—In my original letter, the following was the wording—"As regards suggestion 2, it appears the memorialists are thoroughly unacquainted with the manner in which examiners are appointed. "Poo'in'* and scartin'† has been termed Scotch wooin'," thus the memorialists may be misunderstood; meaning, not that the memorialists may be misunderstood because they knew nothing of the manner of appointing the examiners, but that snarling being considered equivalent to Scottish courtship, our English brethren might mistake this quiet hint on the part of the memorialists of the wish to become examiners, for a malicious attack on the Edinburgh examiners, giving as my reason for this conviction, that one of the memorialists had successfully pursued a similar course as regards the Edinburgh Council. Unfortunately the words ("Poo'in' and scartin' has been termed Scotch wooin'") were left out of your issue on the 17th (no doubt owing to the indistinctness of the writing), thereby changing the meaning of the sentence. I think that the memorialists, when they said that the manner in which the Scotch examiners were chosen was unfair, etc., merely meant that they were chosen non-Fairlie, thereby showing their keen conception for a joke, as I never believe Mr. Fairlie could condemn his own conduct as member of the Edinburgh Council. Mr. Frazer, in your issue of the 24th, seems annoyed because Mr. Mackay should have procured a copy of the memorial previous to himself, but who could have imagined anything more ridiculous than that Mr. Frazer went to London with the intention of presenting a memorial without first having obtained a copy of it in Glasgow.

I consider it was the duty of Mr. Mackay to procure a copy of the memorial as early as possible, out of justice to his Edinburgh brethren. Mr. Frazer's conduct on this occasion shows that he is determined to act under the power of a certain clique and support their ideas, whether he understands them or not, more especially when these cast discredit on his own conduct as member of the Edinburgh Council, and that he is not an independent acting member of the London Council, as I always presumed him to be.

Mr. Frazer also states in his letter that the subject has been discussed by the trade here for the previous six months. Allow me to say he is mistaken; the first motion regarding it only being brought before the Glasgow Chemists and Druggists' Association a few weeks ago.

I think it is time that this mania of saddling the examinations as the cause of scarcity of assistants was abandoned, more especially the absurd ideas that the manner in which the examiners are appointed have anything to do with preventing young men from entering the business. The examinations may drive some from the business, but they are those who should never have entered it. A case came under my notice where an employer railed on the examinations because his best counter hand had left for the oil trade; but he remained wilfully oblivious of the fact that his assistant received £120 per annum in the oil trade, with better future prospects, against £80 in the drug trade. Had the case been reversed, and the assistant been offered £120 in the drug trade instead of £80 in the oil trade, would the examinations have deterred him? I think not. I could adduce many similar instances, but refrain, it being a well known fact here that however degrading and demoralizing a business may be (and I can conceive of nothing more degrading and demoralizing than retailing hair oil and confections on Sundays for the benefit of the pockets of pious Christians) you can procure the men provided the remuneration is sufficient for their labour.

Mr. Fairlie states in his report of the last meeting of the Glasgow Chemists and Druggists' Association that Mr. M'Cann's motion to the effect that none but those who close their places of business at 8 P.M. should be eligible to hold office in the Association was lost by a large majority; but I may state that though the members voted against the motion they showed an amicable feeling towards it. One gentleman, though objecting to the motion, stated that the members had the power to elect for office-bearers whom they chose, and that they should only elect early closing men—which undoubtedly they did, leaving only the secretary, and if he had not been envious of position he would never have accepted it after the remarks at the meeting that none but early closing men ought to be office-bearers in a society one of whose main objects is early closing. As a large bulk of new blood is thus infused into the Council of the Glasgow Chemists and Druggists' Association, I am confident that they will treat that compilation of ignorance and calumny known as the Glasgow memorial in the manner it deserves.

I shall not again encroach on your space regarding this subject, as to lay plainer before the supporters of the Glasgow memorial the real cause of the scarcity of assistants would, to use a metaphorical phrase, be "casting pearls before swine."

April 26, 1875. ASSISTANT.

* Pulling. † Scratching.

Sir,—The letter of "Ph. C." in your last issue touches upon a subject that demands the careful attention of all engaged in the business, and which will form the matter of this communication. I allude to the system of medical men keeping open shops. These shops are invariably conducted by unqualified persons, and in direct violation of the Pharmacy Act.

Had this formed the subject of the Glasgow memorial it would have struck at the root of the evil, and the memorialists would have earned the best thanks of the trade. I have no hesitation in affirming that if this is to be tolerated the Pharmacy Act will, in Scotland, become a dead letter. No one will care to spend time and money in obtaining qualifications when businesses are carried on without them. It not only prevents many a young man from entering the business, but also many more remaining in it from attaining their just measure of success. The memorialists make a great mistake in connecting the scarcity of assistants with the examinations and the examiners. A higher rate of salaries must be given; but the question arises, How is this to be done whilst the vitals of the trade are surreptitiously sucked by members of another profession and the infliction tamely submitted to? I can say from personal experience that the examinations at Edinburgh are well conducted by excellent men. They are stringent, but no more so than they ought to be. Still, stringent examinations for the chemist, so long as the doctor has his open shop kept by an unexamined assistant or apprentice, cannot inspire young men with a liking for the trade, or with confidence in the pharmaceutical executive. On Glasgow, with its one hundred and twenty "doctors' shops" and its sixty chemists' shops, it is superfluous to comment. The Council must take up the subject—it cannot with false delicacy be glossed over or shelved. The time is now arrived for a full inquiry, and if action has to be taken the trade will unanimously support it.

April 26, 1875. A SCOTCH PH. CHEMIST.

THE SALARIES OF ASSISTANTS IN THE WEST OF SCOTLAND.

Sir,—Two words seem to be omitted from Mr. McCann's note, which may be better understood by English pharmacists when it is known that all, or a very great majority, of assistants in Scotland are "out-door assistants."

OBSERVER.

COMMUNICATIONS, LETTERS, etc., have been received from T. Jackson, P. Wells, O. Corder, Garside, W. Bird, F. B. Bingley, H. Gilman, S. Taylor, "Minor," "Competitor," X. L., T. D. F., A. P. S., E. J. B., J. B. L. M.

A NEW METHOD OF DETECTING AND ESTIMATING ALUM IN BREAD AND FLOUR.

BY J. C. THRESH.

There are several well-known processes now employed for the above purpose, but I think all who have employed them will acknowledge that a process combining accuracy with dispatch is still a desideratum. Some of the processes published give very inaccurate results, and others are extremely tedious or require great manipulative skill for their successful execution. For some time, I have given special attention to the subject, and I believe that my endeavours to discover a method giving accurate results and requiring but a tithe of the time required by other methods have been crowned with success.

The following details will enable any one to estimate the alum in bread or flour in a few hours, and as will be evident by a little contriving a dozen or so samples may be examined in a day:—

Take 1250 grains of bread (from middle of loaf) or flour, and char thoroughly in a platinum dish or on foil over a gas lamp. Powder the char and mix it with sufficient pure strong hydrochloric acid to make a thin cream. Boil gently for a few minutes, then add about 100 c.c. of water, and continue the ebullition a few minutes longer. Dilute to 150 c.c., stir well and filter off 120 c.c., which will contain the aluminia from 1000 grs. of the bread or flour. To this filtrate, add a slight excess of solution of ammonia, boil for a few seconds, then let the precipitate subside, and decant the supernatant fluid. Add boiling water to the sediment and again set aside to settle and decant the clear fluid. Pass the fluids through a small filter to collect any particles of the precipitate which may have been suspended therein, and throw the filtrate away. Now add to the partially washed precipitate about a gramme of pure caustic potash (or soda), warm and pass the solution through the same filter employed for the previously decanted fluids. Wash the filter with hot water to which a little KHO may be added, and proceed to precipitate the aluminia in the filtrate by adding a few drops of dilute phosphoric acid and excess of pure acetic acid. Heat the solution and precipitate to the boiling point, and then wash the latter by decantation and filtration. Finally dry, ignite, and weigh. The weight of the resulting $AlPO_4$ in grammes multiplied by 400 will give the amount of ammonia alum in grains present in one pound of the bread or flour.

The following six analyses prove the accuracy of the results obtained by this method:—

	Quantity of Alum added to 1lb. of bread or flour.	Amount of $AlPO_4$ obtained from 1000 grs. of the same.	Amount of Alum in 1lb. calculated therefrom.
Exp. 1.	2·8 grains.	·0065 grammes.	2·6 grains.
„ 2.	8·4 „	·02075 „	8·3 „
„ 3.	14·4 „	·036 „	14·4 „
		FLOUR.	
Exp. 1.	16·8 grains.	·041 grms.	16·4 grains.
„ 2.	5·6 „	·013 „	5·2 „
„ 3.*	10·2 „	·023 „	9·65 „

The flour experimented on did not contain a trace of aluminia in its composition, and the bread employed was made from the same flour. The alum was added to 1250 grs. of bread by making a standard solution and dropping from a carefully graduated burette certain noted quantities upon the bread previous to burning it. With the flour the alum was intimately mixed previous to charring. It is evident, therefore, that the temperature at which the bread or flour is burnt does not render the aluminia insoluble in strong hydrochloric acid, and it is equally evident that by precipitating the alumina as phosphate by addition of acetic acid, neither silica nor magnesium phosphate are co-precipitated with it.

Previous to adopting this process, I tried a modification of it, which consisted in using solution of potash instead of ammonia, but I found that the results were much too low. However, if the HCl employed to dissolve the salts from the char be almost entirely dissipated by evaporation on the water-bath, and the experiment then conducted according to this modification, the results are much more accurate, though still too low. Thus, two analyses by this method gave $AlPO_4$ representing 10 grs. and 5·2 grs., respectively, of alum to 1lb. of bread, whereas 11 grains and 6·15 grains had been added to the samples

Buxton, April 3rd, 1875.

* In this experiment, potash alum had been added, and to determine the quantity present in the lb. of flour the weight of the $AlPO_4$ (in grammes) is multiplied by 418·8.

VANILLA.

BY JOHN R. JACKSON,

Curator of the Museums, Royal Gardens, Kew.

Vanilla, now seldom, if ever, used in medicine, has an amount of interest attached to it owing to its natural affinities, early history, commercial value and uses, that may render some notes on the subject worth recording.

There has lately been issued from the French press a pamphlet of some fifty odd pages, devoted entirely to the consideration of the vanilla plant in all its bearings. Considering, however, that the author is a member of the Chamber of Agriculture of Reunion, a good deal of the book is devoted to vanilla as a product of that island. Nevertheless, it is a valuable addition to the literature of the subject. Its title is 'Étude sur la Vanille,' par A. Delteil.

How many, and what are the exact species of vanilla which furnish the commercial article, has always been a question amongst authors ever since that genus itself has been known. It will be well, however, to trace the history of the vanilla and then to point out the opinions of more recent writers. The plant being, as is well known, a member of the *Orchidaceæ*, was pretty fairly described by the old writers. Thus Pomet says, in his 'Compleat History of Druggs,' that the pods or cods of about half a foot long, of the thickness of a child's little finger, hung upon a plant of twelve or fifteen feet high, that climbs like a creeper; for which reason they grow most frequently upon walls or at the roots of trees, or else upon props or the like where they are supported. They have round stalks, disposed in knots like the sugar cane; from each knot there puts forth large thick leaves, about a finger's length, which are as green as the stalk, and fall off or wither away, as the great plantane does, after which come pods that are green at first, yellowish afterwards, and grow browner according as they ripen."

Originally a native of Eastern Mexico, it was in early times used by the natives to flavour their chocolate. It was brought to Europe by the Spaniards, but little seems to have been known about it or its uses till the middle or perhaps the latter part of the seventeenth century. Pomet says, however, that the "*Vanilla's* are much used in France for making up chocolate, and sometimes to perfume snuff,"—the former being at the present time one of its chief applications, but the latter, so far as we know, having quite died out. Many varieties of vanilla are known in commerce, but as of old, the Mexican sort is considered the best. At one time, *Vanilla aromatica*, Swartz, was supposed to be the plant from which most, if not all, the vanilla of commerce was procured. Pereira mentions five species as probably contributing "some of the vanilla of commerce," namely, *V. planifolia*, Andrews, *V. aromatica*, Swartz, *V. guianensis*, Splitberg, *V. palmarum*, Lindl., and *V. pompona*, Schiede. By some authors *V. sylvestris*, Schiede, and *V. sativa*, Schiede, have also been considered good species yielding some of the best Mexican vanilla. Dr. Pereira, however, considered them as varieties of *V. planifolia*. M. Delteil, in the pamphlet before alluded to, refers Mexican vanilla to the following species:—*V. sativa*, *sylvestris*, *planifolia*, and *pompona*; Guiana and Surinam to *V. guianensis*; Bahia to *V. palmarum*; and that from Brazil and Peru to *V. aromatica*. The most recent authority, however, and a very trustworthy one, namely, the 'Pharmacographia,' of Professor Flückiger and the late Mr. Hanbury, gives the botanical origin of vanilla simply as *V. planifolia*, Andrews, and refers to no other species. Though indigenous to Mexico, vanilla is cultivated, as will be seen from the foregoing remarks, in various parts of tropical America, and has been successfully introduced into the Mauritius and Reunion, from whence large quantities are annually imported. Java also grows vanilla to a considerable extent. To the cultivator it is a remunerative crop in situations where climate and atmospheric conditions are suited to it. It is very easy of cultivation by fastening shoots to the trees, into the bark of which they soon strike their roots, growing luxuriantly, bearing fruit when they are about three years old, and continuing to do for about forty years. Under natural conditions the flowers are impregnated by insect agency, but artificial fecundation is frequently resorted to,—indeed it is one of the principal points of consideration in M. Delteil's work.

The gathering and drying of the pods as described by Pomet differs in some respects from the descriptions of modern writers. "When they are ripe," he says, "the people of Mexico, those of Guatemala and St. Domingo, gather them, and hang them up by one end in the shade to dry; and when they are dry enough to keep, they rub them with oil to hinder them from drying too much, and prevent their breaking, and then they put them up in little bags of fifty, a hundred, or a hundred and fifty to bring them hither. Nevertheless, there are some who value their gain more than their conscience, who let them hang upon the stalks till over ripe, and receive from them a black fragrant balsam, that flows till the essential part of the *vanilla* is exhausted, and it can run no more; and then they gather the pods, and pack them up for sale as aforesaid." The plan now adopted is to gather the pods before they are quite ripe and to allow them to ripen by alternately wrapping them in cloths and exposing them open to a moderate degree of heat. This process is said to preserve or develop their full fragrance. When ready for exportation they are made up into bundles and wrapped in paper. What the "black fragrant balsam," of which Pomet speaks, could have been used for, we have no record; indeed, referring to it in another part of his article, he says, "As to the balsam, the Spaniards keep that, for we have none of it brought to us." His advice, with regard to the choice of vanilla holds good at the present time. On this point he says, "Choose such as are well fed, thick, long, new, heavy, not wrinkled, or rubbed with balsam, and which have not been kept moist, but of a good smell: and beware of those that are small and dry, and of little smell." The Mexicans in early times appear to have been very fond of the vanilla flavour in their chocolate, indeed, we are told that they were "mighty lovers of these plants."

With regard to the odorous principle of vanilla it is shown in the 'Pharmacographia,' that it is not contained in the fleshy exterior portion of the pod but in the interior alone. Its use is chiefly for flavouring chocolate and confectionery. It fetches a high price, and its imports are necessarily small when compared with other commodities.

LIQUOR SENNÆ.

BY PERCY WELLS, M.P.S.

In the *Pharmaceutical Journal* of the 24th April I notice there is still a want of a good and efficient preparation of senna.

The formula which I append has been used by me for a period of twenty-seven years, and in no single instance has the preparation been ever known to fail as an active but not griping purgative.

Mix 13 ozs. water, 3 ozs. rectified spirit, and 30 minims of liquor potassæ and pour it over 6 ozs. of small sifted Alexandrian senna. Keep the jar corked and stir once or twice daily for seven days, then submit to strong pressure and strain the liquor through fine muslin or calico. In about a week there will be a slight deposit, from which the clear liquid may be decanted and the residue can be filtered.

One part of this liquor mixed with three parts of water forms a preparation equal to infus. sennæ, P.L.

East Brixton, S. W., April 26th, 1875.

THE ACTIVE PRINCIPLES OF THE OFFICINAL VERATRUMS.*

A Chemico-Physiological Study.

BY CHARLES L. MITCHELL.

Part III.—Physiological.

(*Concluded from page* 868.)

Exp. No. 6. Small kitten. Veratralbia Injected $\frac{1}{150}$ grain; vomited in half an hour; appeared depressed; remained perfectly active; no paralysis; no change in pulse or respirations.

Exp. No. 7. Injected into vena cava descendens $\frac{1}{15}$ grain veratralbia. Before injection, pulse 160; respirations, 30. After $1\frac{1}{2}$ min., heart 112; two inspiratory gasps since injection. 3 min. Heart 90. 8 min. Auricles still beating; respiration has ceased entirely; ventricles of heart contract very slightly. Artificial respiration by means of blowpipe in trachea was commenced. A notable increase immediately occurred in the force of the contractions of the auricles and ventricles. Slight cardiac contractions for more than an hour. No post-mortem was made.

* Read before the American Pharmaceutical Association. Reprinted from the 'Transactions.'

Experiment No. 8 (*J. R. H.*). *Dog, weight* 14 *pounds.*

Time.	Heart.	Respiration.	Temp.	General Symptoms.
Before Injection.	104	28	101·2°	Injected in thigh $\frac{1}{20}$ gr. veratralbia
1½ min.	..	Very rapid, panting.	..	Ran across room, staggered, fell on side, got up and walked with difficulty when called.
3½ "	52	24	..	Vomited copiously; avoided operator.
10 "	44	12	..	Intense retching; seeks corner.
12 "	35	10	..	Loose stool; intense retching; lies on belly.
22 "	40	Interrupted. 18	..	Walks to corner when put on feet; pupils natural.
27 "	48	22	101·2	Salivation.
31 "	Regu'ar for two or three beats, then very irregular.		..	Walks when compelled; lies in any position in which placed; groans.
37 "	140	..	..	Paralysed; sprawls when put on feet.
39 "	176	9½	..	Retching.
45 "	..	..	..	Slightly more power; retching.
50 "	180	Very irregular.	..	Conjunctiva sensitive; pupils dilated.
55 "	Cannot be felt.	One convulsive gasp per minute.	96°	Pupils somewhat contracted.
57 "	..	..	..	Dead.

Autopsy. 3½ hrs. after death. Rigor mortis marked. Lungs congested with venous blood. All veins leading to and from heart distended with black blood; heart, left cavities filled, right cavities distended with black blood; liver very much congested, black; spleen, ditto; stomach, intensely congested, walls bathed with bloody mucus; small intestine filled with bloody mucus, walls softened and highly congested; kidneys congested; brain congested, red points appear on section; spinal cord but slightly congested.

Experiment No. 9 (*C. L. M.*). *Large Male Cat, weight* 16 *pounds.*

Time.	Heart.	Respiration.	Temp.	General Symptoms.
Before Injection.	120	36	102°	Injected 1·40th gr. veratralbia.
2 min.	110	38	..	Bites at wound; tries to hide in corner.
10 "	70	24	..	Nauseated.
12 "	..	Very rapid.	..	Vomiting.
20 "	50	20	..	Intense retching; tries to hide.
30 "	45	18	..	Loose stool, and then violent purging.
35 "	40	Interrupted.	..	Lies on belly; retching; salivated.
45 "	35	14	100°	Can hardly walk, lies in any position in which placed; cries.
50 "	50	22	..	Paralysed; sprawls when placed on feet.
60 "	100	Interrupted and very irregular.	..	Convulsions in which the rigidity lasts for several minutes.
80 "	130	10	..	Completely paralysed; groans.
100 "	180	6	99°	Slightly more power; retching.
120 "	200	One gasp per minute.	..	Pupils somewhat dilated.
140 "	..	Resp. ceased.	98°	Pupils contracted.
180 "	Heart, which had been beating much more slowly, stopped entirely.			

Autopsy. 5 min. after death. Marked muscular irritability; muscles shrinking and quivering when cut; lungs congested; veins and heart distended with thick black blood; liver engorged with blood and almost black; stomach intensely congested; small intestine filled with bloody mucus, much softened and congested; marked contraction and dryness of lower portion of large intestine.

Some seven or eight other experiments tried on dogs and cats gave the same general symptoms as noted in the foregoing experiments, the intensity of the gastro-intestinal inflammation varying with the length of time before death. The autopsy of those animals whose death was the slowest exhibited the most intense hyperæmia and gastro-intestinal irritation. These results bear out very closely the effects of veratrum album on the lower animals, described by Oulmont.

When a poisonous dose of veratralbia or one of its salts is injected into the tissues of a warm-blooded animal, the first symptom noticed is one of prostration and weakness, the animal manifesting a desire to be quiet. The pupils are normal, and it appears perfectly conscious. The next symptom is a marked quickening of the respirations, attended by an increasing uneasiness and nausea. The respirations gradually become more and more laboured, the nausea increases, and finally the most violent vomiting ensues. This continues at intervals, attended with profuse salivation, and often copious discharges from the bowels. Meanwhile the respirations become less and less frequent, and very irregular, the animal faintly moans and cries, and gradually becomes completely paralysed, losing all power of reflex action. The limbs are generally relaxed, although sometimes a slight disturbance will cause convulsions, in which they remain rigid and extended for several moments. These convulsions are often absent, and are, I think, to some extent regulated by both the animal and the size of the dose. I have noticed them much more in cats than in dogs. The paralysis continues, the respirations become more and more faint, until at length death closes the scene. During all these stages the animal retains consciousness. The heart continues to beat some time after cessation of respiration. The autopsy discloses marked congestion, and generally the most violent inflammation of the stomach and intestines. These symptoms are varied by the dose, a large amount causing almost instant convulsions, paralysis, and death, without any of the intestinal disturbances.

The question which immediately arises is, how does veratralbia produce death? Through the respiratory system, the heart or the brain? It is evident that it is not of cerebral origin. It must, therefore, be either through the respiratory or the circulatory systems. In experiments Nos. 7, 8, 9, the heart continued beating some time after the cessation of respiration. Death was caused by asphyxia, the result of a failure of the muscles of respiration. In very large doses there is just the reverse of this. The respirations are comparatively unaffected, while the action of the heart is almost immediately stopped (see experiments 4, 5), and death is probably caused by its suspension. After death the heart is found contracted, and in experiment No. 6 the auricles were found filled respectively with venous and arterial blood, while the ventricles were almost bloodless, hard, and contracted. That veratralbia acts as an arterial sedative is shown by the fall of the pulsations, and the temperature. One curious fact remains to be here noted. The arterial pressure gradually diminishes until a certain stage is attained, after which it gradually increases, and finally exceeds its pristine force, and then gradually falls, the pulsations continuing some time after respiration has ceased. That this is probably due to asphyxia is proved by the fact, that in experiment No. 7 artificial respiration produced an immediate quickening of the heart's action. Its effect on the alimentary canal is more difficult to explain but is probably due to a paralysis of the vaso-motor nerves.

Exp. No. 10. (*J. R. H.*) Divided the cord in the neck of two half-grown frogs, and into one injected $\frac{1}{100}$ grain of veratralbia.

Time.	Frog (with injection of Alkaloid.	Time.	Controlling Frog.
3m. 30s.	Acetic acid 36 per cent. causes no movement in other leg.	3m. 30s	Causes motion.
8m. 30s.	Apparent period of muscular excitation, muscles of posterior extremity deep red, and respond feebly to galvanic current.	8m. 30s	Muscles of posterior extremities respond actively.
12 min.	Muscles almost paralysed, respond still more feebly.	12 min.	Muscles almost white, respond freely.

Gastrocnemius nerve placed in sol. alkaloid (gr. iij to aq. f℥j), diminished action; action in $\frac{1}{2}$ minute; and complete paralysis in $\frac{1}{2}$ minute.

This experiment would tend to coincide with those of Dr. Wood, and to prove that veratralbia is both a muscle and a nerve poison, very much resembling veratria. I therefore conclude that veratralbia acts as,

I. A local irritant.

II. An irritant emetic and cathartic.

III. A direct depressant to the circulation.

IV. A powerful nerve and muscle poison, producing death by either paralysis of the respiratory nerves, or by a sudden paralysis and suspension of the action of the heart muscle. Its action on the nervous system has not been studied. It is probably a spinal motor depressant, like the other alkaloids of this group.

I therefore conclude in answer to my queries—

I. There exists no such alkaloid as viridia.

II. Bullock's viridia is identical with and probably was jervia.

III. There is a distinct alkaloid in veratrum album. differing from both veratroidia and veratria.

IV. The resin of veratrum album is in itself nearly inactive and owes whatever power it may possess to the presence of veratralbia.

V. The alkaloids do not exist in sufficient proportion to be profitably extracted.

VI. Jervia does not exist in veratrum sabadilla seeds.

VII. Jervia and sabadillia are probably not identical.

VIII. Couerbe's "Le Veratrin" is a mixture of resin and veratria.

IX. If the reader has carefully gone over my paper any answer to this question, further than "Yes," is unnecessary.

In conclusion, I desire to express my thanks and deep indebtedness to Dr. H. C. Wood, jun., for the physiological studies to which this paper owes so much of its value; and for counsel and advice in what was to me a novel and difficult line of research. My thanks are also due to Dr. Haynes for his valuable assistance.

THE DECOMPOSITION OF SOME SALTS BY WATER.*

BY M. DITTE.

In the first of two notes recently presented to the French Academy of Sciences, the author gives the result of an investigation into the action of water upon sulphate of mercury (HgO, SO_3). In contact with water at ordinary temperature the sulphate of binoxide of mercury immediately becomes coloured, subsulphate ($3HgO, SO_3$) is precipitated, and the water becomes strongly acid. The reaction continues upon the addition of the neutral salt until the proportion of sulphuric acid set free attains a certain limit, when the liquid no longer decomposes, but simply dissolves the sulphate until saturated.

By experiment, M. Ditte has found that at a temperature of 12° C. water which contains less than 67 grams of free sulphuric acid to the litre decomposes the neutral salt, takes up the acid set free, and becomes saturated with subsulphate. As soon as the water contains more than 67 grams of free sulphuric acid to the litre it loses all chemical action upon the neutral salt, and dissolves it without decomposition. The neutral salt is even reproduced if there be an excess of subsulphate; so that whatever may be the starting point the final result is a liquor containing 67 grams of acid to the litre, provided that the temperature remains the same. But the liquor which at 12° C. ceases to decompose the neutral salt, attacks it again and becomes coloured yellow if the temperature be raised. The presence of another acid in the liquor does not affect the phenomenon.

The second note of M. Ditte was relative to the action of water upon nitrate of bismuth, subnitrate of bismuth, and protochloride of antimony.

At the ordinary temperature crystals of nitrate of bismuth (BiO_3, $3NO_5$, $3HO$) are immediately decomposed by water, which becomes strongly acid. At the same time a white precipitate is formed which is always crystalline. The crystals correspond to the formula BiO_3, NO_5, with one, two, three, or four equivalents of water, according to the temperature. The decomposition ceases when the free acid reaches the proportion of 83 grams to the litre, after which the nitrate is simply dissolved. If now either water or nitric acid be added the composition of the liquor undergoes modification until this proportion of free acid is restored; the liquor yielding the acid to the subnitrate and reconstituting the neutral salts if the proportion be exceeded, or decomposing the neutral nitrate in solution if it be deficient. Successive additions of water to an acid solution of neutral nitrate determine the precipitation of subnitrate, the liquor always returning to the limit of acidity until all the neutral salt has disappeared.

If a limpid solution of neutral nitrate be heated there is formed a crystalline precipitate of subnitrate, which disappears upon cooling. The cause of this is that the proportion of free acid in a solution which is required in order that the neutral salt be not decomposed is augmented as the temperature is raised; when heated the dissolved neutral salt is decomposed, but upon cooling, the free nitric acid combines with the subnitrate resulting from the elevation of temperature and the precipitate disappears.

Subnitrate of bismuth (BiO_3, NO_5, HO) is also decomposed by water into free acid and a more basic amorphous salt. The decomposition is slight in the cold, but at 100° the decomposition goes on until the water contains about 4·5 grams of free acid to the litre. By exhausting this salt with water a new basic nitrate is formed ($2BiO_3$, NO_5). At a temperature of 100° C. a liquid containing less than 4·5 grams of free acid to the litre immediately attacks the subnitrate and becomes turbid. When the free acid exceeds 4·5 grams to the litre the liquor becomes clear; the acid in excess combining with the subsalt ($2BiO_3$, NO_5) formed, the nitrate (BiO_3, NO_5) reappears with its crystalline form and silvery lustre.

Thus the neutral salt treated with water gives at first the crystalline subnitrate (BiO_3, NO_5), which washed with hot or cold water is converted into a white powder that is a mixture of basic salts ($2BiO_3$, NO_5 and BiO_3, NO_5). After prolonged washing with water a fixed product is obtained which is $2BiO_3$, NO_5.

That which has been said respecting nitrate of bismuth applies also to chloride of antimony (Sb_2Cl_5). It is decomposed by water into a white precipitate of oxychloride (Sb_2O_2Cl) and free hydrochloric acid, until the liquor contains about 159 grams of free acid to the litre, after which it dissolves without decomposition. Any liquor that contains a proportion of free acid below this limit decomposes the protochloride into oxychloride and free acid; any liquor which contains more, on the contrary, produces protochloride. Oxychloride of antimony, like subnitrate of bismuth, is decomposed in its turn, especially at a temperature of 100° C.

The Pharmaceutical Journal.

SATURDAY, MAY 8, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed " Pharm. Journ."*

THE BOTANICAL PRIZE.

LAST week, on Flora's own day, it fell to our lot to publish the official announcement respecting the Silver Medal which is offered by the Council of the Pharmaceutical Society for the best herbarium, collected, under certain conditions, in any part of the United Kingdom, between the first day of May, 1875, and the first day of June, 1876. From the necessity of the case there is a certain amount of monotony attending this and similar announcements, the form in which it is made varying but little from that which was drawn up by the late Mr. HENRY DEANE in 1856, and there is a probability that this monotony is not at all conducive to the multiplication of competitors for the prize. We are, therefore, glad of the opportunity afforded by the letter of a correspondent, printed at p. 903, to direct the attention of our young friends who are eligible to compete to some of the objects contemplated in the institution of the prize, and incidentally to correct some misapprehensions which, we think, are entertained by our correspondent.

Thirty years' continuous effort on the part of the Pharmaceutical Society has worked so great a revolution in opinion as to the nature and extent of the educational qualification desirable in the practising pharmacist, that it is difficult to realize now the circumstances with which, in its earlier years, the Society had to deal. In a day when the special fitness of the pharmaceutical chemist to fill the responsible post of public analyst is generally conceded, we are apt to forget that within a few months of the first herbarium prize being offered, and fifteen years after the establishment of the Society, the late JACOB BELL had to lament that in the chemical investigations connected with the PALMER and other poisoning cases, no pharmaceutical chemists were engaged, as would have been the case in France or Germany, because the only class of persons then competent to undertake such duties in this country were members of the medical profession. And we have it on record that "so little was botany formerly considered an essential branch of pharmaceutical education, that in the early examinations of the Society it was found necessary almost, if not entirely, to exclude it from the Minor examination, and although some of the questions had reference to the botanical characters of plants, it was understood that deficiency in the answers on this subject would not alone be a sufficient ground for the rejection of a candidate."

The prudent foresight of instituting a prize which should stimulate the apprentice to make practical acquaintance with British plants in their habitats, and to acquire sufficient knowledge of the rudiments of botany to enable him to classify and name them correctly, is evident. The young man who, after two or three years of delightful preliminary work, has acquired the skill, knowledge, and confidence that encourage him to send in his herbarium with a hope of success, will find that he has also gone through the best possible preparation for "recognizing the more important indigenous plants" and evidencing his general knowledge of the elementary structure of plants in his Minor examination. Moreover, he will have laid a foundation for the more intimate acquaintance with vegetable morphology and the principles of classification, required in the Major examination, in a practical manner which cannot be equalled by any amount of application to books alone.

Were any confirmation of this opinion required we need only refer to the statement made by Professor BENTLEY, whose name has now for so many years been closely associated with pharmaceutical botany, when announcing the award of the last herbarium prize, that nearly all his knowledge of plants had been acquired in the collection of plants during the early hours of the morning.

Under these circumstances we cannot agree with our correspondent that an apprentice is "necessarily incompetent to make such a collection;" such a conclusion is contradicted by the remembrance of the many excellent collections that have been sent in by apprentices in past years. In fact, one principal merit of the prize seems to us to be that it helps to counteract, so far as botany is concerned, that fatal tendency to put off all real study until the time of "preparing for the Minor." We quite agree with our correspondent that to a man preparing for the Major examination such a collection would be invaluable; but we think that to him its value should and would be sufficiently obvious without the added lustre of a silver medal.

There is one other point in our correspondent's letter, for giving us the opportunity of alluding to which we thank him. It is true that, according to a new regulation, the age of all future associates will necessarily exceed twenty-one years, and consequently they will be excluded from the competition. But this regulation has not been long in force, and there are a few associates who passed under the old regulation who are still under the prescribed age. It will therefore be necessary for the next year or two probably to retain the phrase "apprentices and associates" in the conditions.

A "YOUNG LION OF THE PRESS" ON DOCTORS AND CHEMISTS.

A really marvellous instance of the ignorance that is so often associated with the gushing declamation of the stump orator and the sensational article writing characteristic of certain newspapers has just been furnished by the *Daily Telegraph*, in its editorial comments on the trial for manslaughter at Glasgow reported in our last week's issue.

It will be remembered that the unfortunate young man who committed the mistake resulting in the death of a child and in his being sentenced to three months' imprisonment was not the assistant of a chemist and druggist, but was a licentiate of the College of Surgeons engaged in the employ of a medical practitioner keeping an open shop for the sale of drugs. Nevertheless, the article now referred to in the *Daily Telegraph* starts with the announcement that "if any proof were needed of the terrible danger to which we are continually exposed at the hands of ignorant or incompetent chemists' assistants we should find it in the details" of the case tried before Lord Deas at Glasgow. Hereupon follow a column and a half of remarks in which the positions of medical men, apothecaries, and chemists and druggists, in regard to dispensing medicines, are jumbled together in such a manner as to show that the writer was totally unacquainted with the subject he was attempting to discuss. At the conclusion, indeed, it is admitted that the Pharmaceutical Society discharges its important duties with an integrity and a care which give that Society a distinct claim upon the gratitude of the public; but this statement is mixed up with a reference to the functions of the Apothecaries' Company which shows that the services rendered to the public by the Society are very indistinctly appreciated by the writer.

A NEW THERMOMETRIC SCALE.

At the meeting of the Chemical Society on Thursday evening, Mr. John Williams read a paper in which he proposed a new thermometric scale. After specifying the several defects of the scales now in common use, he proceeded to describe the new one which he had devised. This is based upon the physical characters of mercury, which solidifies at a very low temperature and boils at a very high temperature. Mr. Williams therefore takes the interval between these two points and divides it into one thousand degrees, making his zero the solidifying point of mercury. According to this scale the melting point of ice is 100° and the boiling point of water 350°.

Among the advantages to be derived from such a scale may be mentioned the avoidance of fractions of degrees, since the degrees are very much smaller than those of either the Centigrade or Fahrenheit scales. Another advantage of the Milligrade scale, as it is termed by Mr. Williams, is the doing away with minus degrees while at the same time the indication of temperatures below the freezing point of water is sufficiently distinct, as all numbers below 100° of the Milligrade scale are between 0° and—40° of the Centigrade scale. These are certainly considerable advantages, but it remains to be seen whether they are sufficient to ensure the substitution of the Milligrade scale for those now in common use.

THE SALE OF POISONS.

In connection with the report at page 900 of the prosecution for the sale of poison, it may be as well to mention that the fine inflicted by the magistrate merely had reference to the illegal sale of poison without a label with the word "Poison." The sale of poison by an oil and colourman, however, involves a further infringement of the Pharmacy Act, and renders the vendor liable to prosecution under section 15. We may also call our readers' attention to the fact that at the late meeting of the Council of the Pharmaceutical Society the subject of the illegal sale of poisons was under consideration, with a view to the adoption of active measures for putting a stop to the practice which we referred to last week as being a source of much dissatisfaction among chemists and druggists.

THE ANNUAL DINNER.

We are requested to state that tickets for the Annual Dinner of the Members of the Pharmaceutical Society and their friends, which is to take place at Willis's Rooms, on the 18th inst., may be obtained on or before Friday next, the 14th inst., from any of the Stewards, a list of whom will be found in our advertising pages. After that date, tickets will be obtainable only by application to Mr. Richard Bremridge, 17, Bloomsbury Square.

THE SALE OF ARSENIC IN FRANCE.

It appears that the use of arsenious acid in the pulverulent form, for the medical treatment of domestic animals, has become somewhat prevalent in France, and that veterinarians frequently prescribe it in the pure state. But until recently pharmaciens were prohibited by law from vending arsenic and its compounds for veterinary practice unless combined with other substances according to a yet unpromulgated authorized formula. In order, therefore, to relieve the pharmaciens from their dilemma, the Minister of Agriculture and Commerce has just published a decree, providing that no arsenious acid intended for internal administration to domestic animals shall be sold unless it has been previously mixed with one per cent. of anhydrous sesquioxide of iron (colcothar), and one-half per cent. of powdered socotrine aloes. The three substances are to be rubbed up in a glass or porcelain mortar until they form a perfectly homogeneous mixture.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, May 5, 1875.

MR. THOMAS HYDE HILLS, PRESIDENT.
MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Baynes, Betty, Frazer, Greenish, Hampson, Owen, Radley, Robbins, Sandford, Savage, Sutton, and Williams.

The minutes of the previous meeting were read and confirmed.

Legacy from the late Mr. Daniel Hanbury.

The President read a letter which he had received from Mr. Thomas Hanbury, of Croydon, one of the executors of the late Mr. Daniel Hanbury, stating that he had forwarded to the Secretary a cheque for £90, being a legacy of £100, less £10 legacy duty, bequeathed to the Pharmaceutical Society by Mr. Daniel Hanbury "for the increase of the library." He then moved that the letter be entered on the minutes, and that the subject be referred to the Library, Museum, and Laboratory Committee for consideration on the first convenient opportunity. The President said that, with the consent of the Council, he would also write a letter to Mr. Thomas Hanbury, acknowledging the receipt and expressing their best thanks.

The motion was seconded by the Vice-President and carried unanimously.

The President also read a letter from Mr. Daniel Bell Hanbury, expressing the thanks of himself and family for the sympathy evinced by the Council in their bereavement.

Election of Honorary Members.

Professor Dragendorff, Professor of Pharmacognosy in the University of Dorpat, Russia,
and
Professor Von Trapp, Professor of Pharmacology, St. Petersburg,
were elected Honorary and Corresponding Members of the Society.

The following being duly registered as Pharmaceutical Chemists were respectively granted a diploma stamped with the seal of the Society:—

Blackwell, Josiah.
Broad, John Morris.
Harrington, Arthur.
Holt, George Alfred.
Lambert, William Henry.
Llewellyn, John.
Newhill, John William.
Worthington, William.

Elections.

MEMBERS.

Pharmaceutical Chemists.

Blackwell, Josiah .... Birmingham.
Broad, John Morris .... London.
Feaver, John .... Brighton.
Gordon, John .... Glasgow.
Harrington, Arthur .... Needham Market.
Holt, George Alfred .... Rochdale.
Lambert, William Henry .... Hull.
Laugher, William .... West Bromwich.
Llewellyn, John .... Cowbridge.
Tocher, John .... Glasgow.
Worthington, William .... Preston.

Chemists and Druggists.

Blair, Rose Panton .... Perth.
Burn, David Haitly .... Arbroath.
Silvers, Francis Thirkettle .... London.

ASSOCIATES.

The following having passed their respective examinations, and being in business on their own account, were elected "Associates in Business" of the Society:—

Minor.

Alfred, Thomas .... Stonehouse, Gloucestershire.
Anderson, David Smith .... Forfar.
Barlow, Frederick .... Longton.
Barnes, Francis Joshua .... Liverpool.
Baxter, John Newsome .... Wath-upon-Dearne.
Birrell, George .... London.
Broadbent, Sidney .... Littleborough.
Bryden, John .... Barrow-in-Furness.
Fisher, Sidney .... Liverpool.
Gatenby, Robert .... Bridlington.
Gibbs, Joseph .... Eastbourne.
Harrison, James .... Sunderland.
Harvey, William Sutton .... Margate.
Jones, Alfred .... Scarborough.
Jones, Matthew Henry .... London.
Knight, Alfred George .... Wincanton.
Lewis, Edward .... London.
Lindsay, Robert .... Peebles.
Longley, Joseph .... Sheffield.
Maitland, Pelham Christopher Stonehouse, Devon.
Rogers, William Sexton .... West Cowes.
Smith, John .... Clay Cross.
Smith, Thomas Henry .... Dewsbury.
Stamford, Frederick .... Beverley.
Steele, Samuel .... Plymouth.
Thorp, John .... Longsight.
Tully, John .... Rotherfield.
Vigis, Joseph Lewis .... Bath.
Watson, William .... Rochester.
White, Charles Edwin .... London.

Modified.

Althorp, Henry .... Peterborough.
Andrew, Ablett Ashworth .... Atherton.
Clement, John Radford .... Egremont.
Entwisle, John Bell .... Liverpool.
Evans, Daniel Ogilvie .... Farnworth.
Godolphin, George Frederick A. London.
Gowen, Albert .... Ringwood.
Hitchin, Robert .... Burnley.
Jackson, John .... Bradford.
Manthorp, Frederick William ... Colchester.
Pettinger, Elmer .... London.
Pettman, Richard .... Margate.
Pratt, Thomas Henry .... Newbury.
Ramsden, William .... Fallowfield.
Toone, John Alfred .... Cheltenham.
Westlake, John .... Sutton.
Wright, Arthur .... Lowestoft.

The following having passed their respective examinations were elected "Associates" of the Society:—

Minor.

Barrett, Josephus Teague .... Devenport.
Beale, James Hawkins T. .... Camden Town.
Berry, Henry Burton .... Gloucester.
Cant, Hemington .... Stratford.
Case, William .... Norwich.
Chadwick, George Nicholas .... Dewsbury.
Clegg, Edmund .... Manchester.
Cocker, Justus John .... Over Darwen.
Dodd, William Henry .... Fulham.
Ellis, Henry .... Rochdale.
Highmoor, George Samuel .... Leeds.
Illsley, Thomas Brown .... Belper.
Jones, Charles William .... Ashby de la Zouch.
Martin, Henry Stephen .... Brighton.
Pasmore, Walter Frank .... London.
Phillips, James Arthur .... Penge.
Royse, John Frederick .... Stockport.
Saville, George .... Wakefield
Sawyer, Henry .... Carlisle.
Senier, Alfred, jun. .... Finsbury Park.
Slater, Thomas, jun. .... Stone.
Spilsbury, James .... Stafford.
Vaughan, John .... Newtown.
Vernon, William Henry .... Boston.
Widdowson, William .... Nottingham.
Williams, William .... London.

Modified.

Hall, Frederic John ....Leamington.
Smith, Robert George ....Liverpool.

APPRENTICES.

The following having passed the Preliminary Examination were elected "Apprentices or Students" of the Society:—

Batty, Edward ... .Ilkley.
Blades, Arthur Mowbray.........Northwich.
Botwood, Charles Walker ......Great Bridge.
Butler, Christie Havelock ......Tooting.
Chapman, William Henry ......Birmingham.
Edmond, Francis Edward ......Scarborough.
Evans, Benjamin ....Liverpool.
Foster, Ferdinand Green.........Landport.
Holden, Austin Caley ....York.
Holland, Henry ....Leftwich.
Holloway, Robert..... ....Maidstone.
Jones, Joseph Humphrey ......Wolverhampton.
Llewellyn, Thomas .... Pembroke.
Lubbock, John William ....London.
McNeilage, Alexander ....Greenock.
Maconachie, Andrew Wyllie ...Glasgow.
Madden, Ronald George ....London.
Mason, Florus ....Broughton.
Millington, Walter Thomas ...Chester.
Mordue, William ....Haydon Bridge.
Ninnis, Thomas Martin ....Truro.
Parker, Charles Henry M. ......South Molton.
Pratt, William Edwin ....Newtown.
Pridmore, Walter Snape ....Hinckley.
Savory, John Field ....London.
Stone, Fredk. William Stanley Bristol.
Symington, Archibald ....Helensburgh.
Thomas, William Hendy.........Penryn.
Whitaker, Thomas ....London.
Whittaker, Joseph ....Salford.
Whyte, James Samson............Montrose.
Winpenny, Frank Walter ......Barnard Castle.
Womack, Frederick ....Bayswater.
Wright, John Charles ....Wolverhampton.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

LIBRARY, MUSEUM, AND LABORATORY.

The report of this Committee, which had held several meetings, was read. It comprised a recommendation that the following books be purchased for the library:—

'Buek's Index to De Candolle's Prodromus,' 'Manchester Science Lectures.'

The librarian had reported that the average attendance during the preceding month in the library had been during the day, 21; evening, 8; evening attendance in the conversation room, 5·3. The circulation of books had been 146 in town, and 66 to country, to 32 places. The curator had reported that the average attendance in the museum had been, in the morning, 17; evening, 5. The average of daily visitors had been 4. The catalogue was being proceeded with as rapidly as possible. Since the death of Mr. Daniel Hanbury, the proofs had been revised by Professor Bentley alone, but Mr. J. E. Howard had consented to revise that portion relating to the cinchona barks. Professor Bentley had reported that about 50 students had entered his class, the attendance being from 35 to 40 at the lectures and weekly examinations; 7 students had taken perpetual tickets. He stated his opinion that if students attended one course of lectures at Bloomsbury Square, and one on practical botany, they would have an opportunity of acquiring as much information as could have been obtained by attending a full course under the old system. Professor Redwood had reported that the number of entries in his class was about 50, and the attendance at lectures and weekly examinations from 35 to 40. Each course of lectures comprised the whole syllabus. The 'Historical Sketch of Pharmacy' he hoped to be able to complete during the autumn recess. Professor Attfield had reported that he had had 91 entries in the laboratory during the present session, 52 students now being at work. Mr. Greenish had presented a report, which he had prepared at the request of the Committee, on the microscopes belonging to the Society. The Committee had drawn up the annual report which was now presented to the Council.

The Council considered the report in detail, and having made a few verbal alterations agreed to the same.

The report of the Committee was then received and adopted.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts ordered to be paid.

HOUSE.

This Committee reported that it had considered several matters of detail in connection with the arrangements for the supply of gas to the various rooms, and for the prevention of fire. The report was received and adopted.

BENEVOLENT FUND.

This Committee presented a report recommending that the following grants be made:—

£15 to the widow of a registered chemist and druggist at Hull, with four children dependent upon her.

£10 to a registered chemist and druggist, aged 67, formerly a member of the Society.

£5 to the widow of a registered chemist and druggist, in business at various places for fourteen years. The applicant has seven children dependent upon her, and £20 was granted last year to assist in getting one of them into the London Orphan Asylum.

£10 to a registered chemist and druggist at Dover, aged 79, formerly for many years a member of the Society. The applicant had received a grant of £15 last year.

Several other applications had been considered by the Committee, and ordered to stand over for further information.

The report and recommendations were received and adopted, and the name of a registered chemist and druggist, formerly a member of the Society, was placed on the list of approved candidates for an annuity.

LAW AND PARLIAMENTARY.

The SECRETARY had reported to this Committee several cases of infringement of the Pharmacy Act in various places. The Committee recommended that the solicitor be instructed to select cases for prosecution, and to take proceedings if he found the evidence sufficient to ensure conviction.

Mr. BETTY thought the evidence in any case should be laid before the Committee before any action was taken by the solicitor.

Mr. HAMPSON said several glaring cases had been brought before the Committee. He believed that hitherto the Council had not been sufficiently alert in the prosecution of those persons who were infringing the Act of Parliament. It took a great deal of time and trouble to get the Act of Parliament, and now it was obtained it was the imperative duty of the Council, whenever it found the Act was being infringed, to immediately step forward and prosecute the offender. It had become notorious that, not only in London, but in Liverpool and many other places, there were hundreds of unregistered persons carrying on business, and if the Council was anxious to maintain the stability of the Society, it must not neglect this important duty. He had recently been conversing with a respectable member of the trade, and asking him to join the Society, but had met with the reply, "What did the Society do? It compelled young men to pass a stringent examination, and when they commenced business it did not protect them in their calling." If the Council hesitated to prosecute now it would bring discredit on the

Society. He should therefore urge on the Council to accede to the recommendation of the Committee.

Mr. WILLIAMS apprehended that the evidence which had come before the Committee would not be sufficient to prosecute upon, but would require to be gone over again by the solicitor. The Committee had received information from certain quarters of what was going on; the question now was whether the Council would ask for more definite proof of what had been stated, or at once place the matter in the hands of the solicitor, and thus probably save both expense and time.

Mr. SUTTON thought the Society would lose both time and influence by not insisting on its rights. He believed it had been too lax heretofore, and he did not believe in having laws unless they were carried out.

Mr. ROBBINS said the Committee had evidence before it that the practice complained of did exist, and it was on that evidence it was suggested that the solicitor should be instructed to proceed.

Mr. BETTY thought it would be well for the Committee to know the steps that were being taken as the cases went on.

The SECRETARY said the solicitor was always very cautious. In fact during the whole time he (the Secretary) had been connected with the Society, no case had broken down which had been taken into court.

The report of the Committee was then received and adopted.

PROPOSED ADDITION TO THE SCHEDULE OF POISONS.

A communication was read from Sir J. D. Astley, M.P for North Lincolnshire, calling attention to a practice prevalent in his own neighbourhood, of administering certain poisonous and powerful drugs to horses, to the serious damage of many valuable animals. He, therefore, intended to introduce a bill into parliament on the subject, and suggested to the Council that it should place in Part 1 of Schedule A to the Pharmacy Act, sulphuric acid, nitric acid, hydrochloric acid, sulphate of iron, sulphate of copper, and several other articles of a similar character.

Mr. HAMPSON thought the best policy in all cases was to give a straightforward answer; and if the Council considered this proposition was not a rational one to say so.

Mr. BAYNES and Mr. WILLIAMS said that it would be impossible to carry out such a proposal.

Mr. RADLEY sympathized to a great extent with Sir J. Astley, as it was becoming a very common practice to give poison to horses.

Mr. SANDFORD said the best way would be to send a courteous reply to Sir J. Astley to the effect that the Council was not able to accede to his suggestions. This view was concurred in, and the Secretary instructed accordingly.

SALE OF FOOD AND DRUGS BILL.

The report of the Special Committee appointed to watch this Bill was read. It included a memorial which had been drawn up and sent to the Local Government Board.

Mr. HAMPSON protested against the action of the Special Committee in drawing up a memorial dealing with the Bill generally, and especially with Dr. Lyon Playfair's amendment, when their instructions were distinctly limited to preparing a memorial with reference to the single point of a reduction of the penalties.

Mr. SANDFORD and nearly every other member of the Council expressed the opinion that the Committee had not gone beyond its instructions, or if it had not confined itself literally to those instructions, had acted entirely in accordance with the spirit of the Council. The report of the Committee was adopted.

PHARMACEUTICAL CHEMISTS AS PUBLIC ANALYSTS.

The PRESIDENT said he had had some correspondence with Mr. Rogerson, of Bradford, which had resulted in that gentleman sending a printed letter to each member of the Council. He would therefore ask the Secretary to read the correspondence. The following is the printed letter:—

"*To the Council of the Pharmaceutical Society.*

"Gentlemen,—In a letter to the President of the Pharmaceutical Society, I ventured to express the opinion that if the question of the appointment of chemists in business as public analysts were discussed by the Council on broad and general public grounds, apart from what might be assumed to be the particular interests of our Society in the matter, the weight of reasoning would be found greater in favour of Dr. Playfair's amendment, disqualifying traders in articles of food and drugs from holding the appointment of official analyst under the Adulteration Act. The President courteously replied that a letter setting forth this view of the subject should receive every consideration at the next meeting of the Council.

"Under these circumstances, I venture respectfully to ask the Council to weigh candidly the fairness or otherwise of the following considerations. It will scarcely be necessary to premise that I have no *personal* motive, but contend solely for a *principle.*

"It is believed, and indeed has in many instances been found in practice, that the effect of appointing as official analyst one member of a trading community is, in the eyes of a large portion of the public, an unquestionable and invidious guarantee of the purity of all articles sold by that analyst in his capacity as a trader. It is not easy, indeed, to escape this inference; for by such appointment the machinery for the local administration of the Act necessarily becomes associated in the mind of the public with a particular shop or store where articles of food and drugs can be purchased direct from the hand of the official analyst himself, which commodities, it is obvious, are practically exempted from the supervision to which those of the analyst's competitors in trade are liable. Consequently, it is held that the *official recognition* of a trader in articles of food and drugs as the local authority in all matters relating to the purity of those substances tends directly to the constant and unjust annoyance and loss of persons honourably carrying on a trade in the same articles, and in the same district, as the public analyst.

"It is evident that appointments of this class introduce a new and seriously invidious element into trade competition, and one which it should surely be the careful aim of a society like ours, in the interest of the great majority of its members and the trade generally, to prevent by every possible means.

"Again, in the event of the analyst's fellow tradesman, and perhaps immediate competitor, being fined on his certificate, the inevitable suspicion that the analyst had acted from private motives must receive considerable colour and support in the minds of the public from the fact of that functionary being himself an open trader in the articles brought to him for his official inspection. Indeed, according to ordinarily accepted ideas of fairness, it is difficult to see how the exercise of the arbitrary powers of public analyst by a *directly interested* person can, in any case, be respected.

"I venture to express the hope that in case nothing weightier than considerations of *expediency* can be advanced in defence of this anomaly, the important *principle* involved in Dr. Playfair's amendment may receive the cordial support of the Council.

"A distinguished member of our Society writes, in reference to this matter, 'Had the Council limited their action to representing that pharmaceutical chemists *not in business* were very suitable persons to fill the office of public analyst, they would have done well.' A petition to parliament, supporting Dr. Playfair's action was, with one exception, unhesitatingly signed by every member of our trade in this town before whom opportunity allowed it to be placed.

"I am, Gentlemen,

"Obediently yours,

"H. G. ROGERSON.

'*Bradford, May 3rd, 1875.*'

The PRESIDENT said he did not think this letter would alter the opinion which had been formed upon this subject, and he believed the Council was nearly unanimous.

Mr. HAMPSON said he would move a resolution—

"That this Council, having given further attention to the amendment of Dr. Lyon Playfair on Clause 9 of the Sale of Food and Drugs Bill, is of opinion that it is not advisable to oppose the amendment in question."

Notwithstanding the Council was in a measure committed to the opposite view to that found in the correspondence, and at the risk of being charged with inconsistency, he would make a few observations in its favour. He must admit that when he first considered this question he did so from a too contracted point of view, and he was led to the opinion which met with most favour round the Board, that it was advisable that pharmaceutical chemists *in business* should obtain the appointment of public analysts. Since then he had given the subject further and more deliberate consideration which had resulted in a totally altered view, and feeling that he had made a mistake in his judgment he thought it only fit and proper that he should acknowledge it, especially as he conceived the mistake made might lead to evil consequences. In judging of the question as to the advisability of appointing pharmaceutical chemists engaged in trade to the position of analyst, the first thing which struck him was this, that a pharmaceutical chemist in business would occupy, in case the proposed Bill become law, a position in which he would be exempt from the operation of the Act. The provisions of the proposed Bill empowered the local authorities to collect samples of drugs, and when they were collected, the collector was to state that they were for analysis. If he wished to be impartial he must call upon the analyst as well as the other chemists,—but what would be the effect? The analyst would simply receive the drug which he himself had sold, and analyse it himself. Such a prospective position is surely too absurd to contemplate. There is no provision in the last Act of Parliament, or in the one proposed for a state of things like this. The fact could not be gainsaid that the particular trader in question would become exempt from the operation of the law. Other and not less important objections could scarcely be better stated than in the correspondence which had been read. They could all see that where an appointment of this kind existed it placed the traders of the district in a very anomalous and delicate situation, because it raised the selected official individual to a more elevated position. His goods were, so to speak, advertised through the medium of police court reports, etc., etc., and the public at length concluded that he was the most select and best of traders in pure drugs. Conditions like these, inequitably produced, would operate unfairly towards neighbouring traders. Mr. Hampson said he should not, however, urge this objection so much as that relating to the inequality of the law to which he had already alluded. He could quite understand how the mistake of the Council had arisen, because he had made the mistake himself. There was no doubt that some pharmaceutical chemists were capable of occupying the position of analyst; that a great many men would be required to carry out the provisions of the new Act, and that it would be difficult for local authorities to find properly qualified men; but still the difficulty remained, that there was nothing in the Act to secure the appointment of efficient analysts. He hoped the question might be rediscussed in a careful and thoughtful manner. They were to some extent responsible for the result of legislation, and it was not too late, as the Bill was still in Committee, and likely to be brought up again shortly, to exert further influence in a different direction if they thought it advisable. He need only add that having come to the conclusion that he had made a mistake, he had written at once to Mr. Sclater-Booth saying he had altered his conviction.

Mr. FRAZER seconded the motion. He said his conclusion was come to on a broad principle of justice. In the neighbourhood of Edinburgh a member of parliament who held an interest to the extent of £35 a year in a small mail steamer was obliged to divest himself of that interest before he could become a member of parliament; and when Sir Sydney Waterlow was elected for a Scotch county he had to resign his seat because his firm supplied stationery to the Government. On the same principle public analysts should be entirely divested of any private interest, which they could not be when carrying on their ordinary businesses. He had written to Dr. Playfair as an old friend, referring him to a report in the Journal as expressing his sentiments on this matter. Mr. Frazer concluded by saying that he had great pleasure in seconding Mr. Hampson's motion.

Mr. SANDFORD said he was not at all prepared for such a motion and should move as an amendment—

"That Mr. Rogerson's letter be allowed to lie on the table."

It seemed to him that the Council could not alter the opinion it had expressed so frequently and for so long a time; for going back to 1872, he found that at that time a deputation waited on Mr. Stansfeld to urge upon him the desirability of appointing pharmaceutical chemists in business as public analysts. The report of the deputation concluded by stating that the President suggested that the objection that a chemist in business might have to analyse articles sold by his fellow tradesmen applied equally to medical men as officers of health, since they might be required to inspect and report upon property in which some of their best patients might be interested. That was a general consideration which applied to the appointment of all analysts. Of course a man might be liable to these influences, but he always understood that for such an appointment not only certain intellectual qualifications, but also a certain character for honesty and independence were required. As to the objection that a gentleman holding office should not derive all the honour and advantage it brought to him, he thought that that was very unsound. They might as well object to Mr. Squire being appointed Chemist to the Queen; and when Mr. Hampson said such an analyst would not be subject to the operation of the Act, he thought any analyst who sold an impure article would very soon lose his appointment. He thought they had committed themselves too far to go back, especially as, in his opinion, they had done so in the right direction.

Mr. WILLIAMS seconded the amendment. He had always spoken in favour of the appointment of pharmaceutical chemists as analysts, but this was in consequence of another opinion which he had also expressed strongly, that the analysts should not be local men, but should be publicly appointed, and should have certain departmental laboratories established throughout the country with a well-qualified staff of chemists to assist in conducting all the required examinations. But he must say so long as the law was as at present, and as long as local bodies had to appoint local men as analysts with small salaries and a great deal of work to do, pharmaceutical chemists ought not to be excluded from this honourable position, which he believed they would carry out honourably and properly. The analyst did not know whose sample it was he was analysing; the articles came to him marked and numbered, and he would not know where they came from. As to the argument produced by Mr. Frazer, he did not think that applied at all. A man was not allowed to be a member of parliament if he was a partner in a firm supplying goods to the Government, because as a member he would have interest which might influence his vote, and he might in various other ways obtain undue preference. But in the case of analysts all this was out of the question. He considered that pharmaceutical chemists had a right to look forward to these appointments and he believed they had in past times too much neglected to look after their own interest. A pure chemist, it was well known, was not quite capable of grappling with all the points involved in questions of pharmaceutical purity, because he was liable to be mistaken in various ways, whilst the pharmacist could make the necessary allowances and understand whether or not the article was unadulterated and sufficiently pure for the purposes of medicine, and, on the other hand, what constituted a real case of imposition and adulteration. He did, therefore, hope that it would not go out to the world that so long as local bodies had to appoint analysts, pharmaceutical chemists, of all other men, should be excluded.

The VICE-PRESIDENT said he had advocated the appointment of pharmaceutical chemists from the commencement, and had attended a deputation to the Local Government Board with reference to it some years ago, and he had not seen any reason to alter his opinion. He might further say that he thought this little trade jealousy which had sprung up at Bradford did not persuade the chemists throughout the country. Some little time ago, in the town of Canterbury, one of their pharmaceutical brethren was appointed by the Town Council as the public analyst. The Local Government Board refused to confirm the appointment, and it was referred back to the Town Council to appoint someone else. The Town Council, however, in his opinion, very properly replied that it had appointed a gentleman in whom it had the utmost confidence, both as to skill and integrity, and it declined to appoint anyone else. The result was this gentleman was appointed analyst to the city of Canterbury. This was about two years ago, and a fortnight since, being in Canterbury, he was in conversation with one of that gentleman's nearest neighbours, and whilst talking over various matters, this appointment cropped up, when his friend had the good sense and honesty to say that he believed his neighbour was the man of all others who ought to have been appointed, and that he himself, though he had been in the habit of doing some little analytical work, now found a great deal of pleasure in handing over such cases as came to him to his neighbour who paid more attention to it. He believed that would be the general feeling, and that if they were to exclude pharmaceutical chemists from these appointments and allowed medical men—because that was the channel in which the appointments would go—to monopolize them, they would not in any way improve the state of matters, and, in many cases, would have gentlemen appointed in whom they, as chemists, would not have so much confidence.

The PRESIDENT said he saw no reason whatever for altering the decision at which he had formerly arrived. He would not take away from pharmaceutical chemists any honour or emolument to which they were entitled; but, on the contrary, would do all he could to aid them in obtaining such rewards for their exertions.

Mr. GREENISH had always considered pharmaceutical chemists, if they possessed requisite medical, chemical, and microscopical knowledge, to be the best men who could be appointed public analysts, and had never seen reason to alter his opinion. He did not think they would be exempt from the operation of the Act, because their drugs could be analysed as well as those of any other person.

Mr. HAMPSON said he had not the least objection to any pharmaceutical chemist holding such an appointment, but he must make a broad distinction between a pharmaceutical chemist holding that appointment alone and being in business at the same time. He thought the training required by a pharmaceutical chemist, if supplemented by further training, was eminently fitted to make him a well qualified analyst, but he must still affirm, in reply to Mr. Sandford, that there were no provisions in the Act of Parliament which would enable that particular individual's chemicals and drugs to be analysed. Again, any man doing a large amount of analytical work must necessarily leave his business to other people, he could not be in the laboratory and in the shop at the same time. He did not think it was fair to put down this memorial to any feeling of jealousy, because before this correspondence took place he had some intimacy with the gentleman who had written the letter, and he was quite sure Mr. Rogerson was too large minded to have been misled by any local or petty motive of jealousy.

Mr. SANDFORD said an analyst was not supposed to know from whom the article submitted to him was brought, and therefore he might have a sample of his own rhubarb taken to him to report upon.

Mr. HAMPSON said the Bill provided that the person buying the article should state that he did so for the purpose of having it analysed, and he must again assert there was no provision in the present or proposed Act which would enable the authorities to take the sample away and have it analysed elsewhere. On the contrary, it was marked in the presence of the purchaser, otherwise the seller would not be able to identify his own article; in fact the Bill did not contemplate any such position.

Mr. FRAZER begged to say that he regretted very much being obliged to vote in favour of Mr. Rogerson's memorial, seeing where it came from, because of his great respect and regard for the public analyst in that town who was a member of the Council.

The amendment was then put with the following result:—

For.—Messrs. Bottle, Baynes, Betty, Greenish, Hills, Owen, Robbins, Radley, Sandford, and Williams.

Against.—Messrs. Hampson and Frazer.

The amendment was therefore carried, and was subsequently passed as a substantive resolution.

THE GLASGOW MEMORIAL.

Previous to Mr. Frazer bringing forward the motion of which he had given notice for referring this memorial to the Law and Parliamentary Committee,

The VICE-PRESIDENT moved and it was unanimously agreed to, that Mr. Frazer's name should be added to the Committee.

Mr. FRAZER then moved his resolution, and afterwards proceeded to read a long paper which he had prepared setting forth his reasons for so doing.

Mr. BETTY rose to order, and suggested that it would be establishing a very bad precedent if members of Council were allowed to read papers at the monthly meetings, instead of making their observations extempore, as had hitherto been the practice.

Mr. FRAZER said he should not bring forward the motion in any other manner, and after a short discussion the objection was waived, on the understanding that the reading of the paper should not be made a precedent. Mr. Frazer then proceeded with his paper stating that though he gave a general support to the memorial he must not be considered as endorsing all the views expressed in it. It had its origin, he believed, in the difficulty found in obtaining educated apprentices and well qualified assistants, and in the fact of many of both classes leaving the trade on account of the character and expense of the examinations. He then went at great length into the details of his own experience to show that this was really the case, gave the history of the memorial, dealt with the objections which had been raised to it, and expressed his concurrence in the recommendation that two opportunities of passing the examinations should be allowed for one fee, and that if candidates had passed in two subjects on the first occasion they should only be examined subsequently in those in which they had failed. In conclusion he said that as there had been quite enough changes of late, he did not wish to advocate any more at present, but if the difficulties now so generally felt continued, he hoped the subject would be fully and fairly considered.

At the conclusion of Mr. Frazer's paper,

Mr. BETTY suggested that in view of the approaching annual elections, which might change the constitution both of the Council and the Parliamentary Committee, the motion should stand over for a month, to which Mr. Frazer consented.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

The sixth meeting of the present session was held on Tuesday, March 16. The chair was taken by Dr. Pile.

Dr. Miller presented a specimen of very white glucose made from wheat, which had a sweet taste, free from any nauseous bitterness. It was stated to have been used as an excipient in pill masses, and in the preparation of syrup of the lacto-phosphates.

Dr. Miller also presented a specimen of cosmolin ointment, closely resembling cosmolin, which had been prepared from one part of paraffin and sixteen parts of lubricating oil; the oil being repeatedly filtered through animal charcoal, and formed into an ointment with the paraffin, by the aid of a water-bath.

In presenting a sample of nearly white salicylic acid, prepared in Berlin, Professor Maisch remarked that the antiseptic properties of this acid might be depended upon only so long as it is in a free state, and until neutralized by the ammonia gradually generated in vegetable infusions. This he thought might explain why oil of gaultheria—salicylate of methyl—is not more effective in preventing fermentation. Mr. Heinitsh said that oil of gaultheria was much used in the United States for the preservation of cider, and appeared to accomplish that object. Mr. Eberle said that oil of mustard was one of the best agents for that purpose, a property which Mr. Lemberger attributed to the sulphur contained in it; but Professor Maisch thought that this could hardly be the case, since the sulphur was present as allyl-sulphocyanide. Mr. Wellcome called attention to the use of phosphate of sodium to increase the solubility of salicylic acid.

Examination of Quinine Sugar-coated Pills.

Mr. Trimble described the result of an examination of seven samples of quinine pills, obtained from prominent manufacturers in Philadelphia. The process followed was to dissolve the number of pills which represents five grains of quinine sulphate in about a fluid drachm of water, acidulated with a few drops of hydrochloric acid. From this solution the quinine was precipitated by ammonia, and the whole was agitated with successive small quantities of ether, which were removed each time by means of a pipette to a weighed watch glass. On evaporation the quinine was left as a gummy mass, which was dried at a moderate temperature and weighed, and the amount of crystallized sulphur calculated. Five samples yielded nearly the full amount claimed for them; a sixth yielded only about 70 per cent. of the quantity represented; while one, the seventh, was found to contain cinchonine hydrochlorate, with a little quinidine, but no quinine. The latter pills were identified by Mr. Trimble as probably being a portion of a large quantity of sugar-coated pills which had been made by a manufacturer who had been supplied with cinchonine hydrochlorate under the name of "French quinine," and had so used a considerable quantity before discovering the fraud. The pills were then thrown upon the hands of the firm supplying the "French quinine," and through various channels had come into the market. The author said there could be little doubt that the several parties dealing in these pills were fully aware of their composition, and he considered that the fact of their continuing to sell them to the trade and the public was disgraceful to themselves and humiliating to the conscientious pharmacist. He was also of opinion that the use of sugar-coated pills had many evident disadvantages, and that the only remedy for the objections to them, as well as other products obtained from the manufacturers, was in the persistent vigilance of the pharmacist.

Dr. Miller read a paper entitled "Official and Officinal," in which he disputed the proposition contained in a foot-note in Attfield's 'Chemistry,' to the effect that the term "official" is more correct than "officinal," when applied to articles contained in the Pharmacopœia. His principal objections were that the two words were both derived from the same root, and the distinction was therefore arbitrary, and that the term 'officinal' has become well established, and its signification is well understood by all pharmacists.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture V.

(*Continued from page 840.*)

On the secondary action of Alcohol on the animal functions, and on the physical deteriorations of structure incident to its excessive use.

Ales.

The practice of adulteration the least hurtful is carried on in ales; that at all events is my experience of the ales sold in London, and I speak from a practical knowledge of the facts. A few years ago a well-known statist asked me to undertake for him a research on the ales sold in London, with a view to the detection of the adulterations in them. For many weeks this gentlemen himself collected beers and ales from different retail houses in the most diverse parts of this metropolis, and neither trouble nor expense was spared in the examination of these samples, in order to arrive at correct results as to the composition of the fluids thus retailed. I may state at once that I did not in any one instance find a truly dangerous adulteration. I found that to many samples common salt had been added, and to some sugar; but the grand adulteration was water, by which the consumer was, if I may so express it, fraudulently benefited and the Government proportionately defrauded. If this aqueous adulteration were not carried on, our registrars of deaths and collectors of revenues would both show heavier totals.

There is a prevailing notion that to malt liquor, bitter substances, such as strychnine, or narcotic substances, such as cocculus indicus, are added. Neumann says that in his time, that is just one hundred years ago, clary, cocculus indicus, and Bohemian rosemary were added to malt liquors in order to increase their intoxicating powers, and he states that the last named substance, Bohemian rosemary, produced a raving intoxication. I know it is also urged, in this day, that there is no known application for

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts*.

the quantity of cocculus indicus that is sold except it be for the adulteration of malt liquors. I will not dispute the matter, but I content myself with stating that I have never detected any foreign body of the kind, and that in the whole of my experience of the effect of malt liquors on man I have never known a symptom produced indicative of the effects of such substances.

The stronger ales and stouts are injurious mainly from the alcohol they contain. Those which have not ceased fermenting, and from which gas is escaping, produce a persistent dyspepsia in those who indulge in them, a dyspepsia attended with flatulency, painful distention of the stomach, and with loss of proper muscular power of the stomach, by which deficiency the trituration of food is impeded and rendered imperfect. At the same time the action of the gastric fluids upon the food is made less effective. There is at the present time in the market a substance used as an addition to ales, which is called *saccharina*. It is sold in the form of the ordinary sugar loaf. It is made by the action of diluted sulphuric acid upon starchy matter, and it is in fact a grape sugar. It gives to the ale body and sweetness. It is in itself a fattening food, and as it is the same as that form of sugar which is found in those who suffer from the disease called diabetes, and which produces the symptoms of that disease, it cannot be taken in quantity without some indirect risk of danger.

Wines.

The evils arising from wines, apart from those which are due to the natural ethylic alcohol they should contain, are derived from several sources. The wine that has not ceased to ferment, and when uncorked is found to be charged with gas, is often as injurious as beer in which the fermentation has not ended. It produces a fermenting process within the body, and gives rise to those phenomena of dyspepsia to which allusion has already been made. Wine that has once been acid and has been treated with lime in order that the acidity may be neutralized, is open to the objection of an excess of salts of lime. It has been urged against wines treated in this manner that they lead to calculous disease when they are taken in quantity for long periods. I must answer to this suggestion that I have not had experience of the slightest evidence that would support it, nor do I think there is sufficient of such wine consumed to warrant any conclusion of the kind. Wine if adulterated with amylic alcohol is unquestionably dangerous, owing to those physiological effects produced by the adulterant to which I specially directed your attention at the second lecture of this course. Wines that are beaded are injurious owing to the foreign mixture for beading that has been added to them, and which I shall describe in due course.

Some substances that form in natural wines exert an effect on the animal body when they are taken into it. These substances are principally aldehyde and acetic acid. Aldehyde when it is present in wine communicates to it a natural bouquet. You will find on the table a pure specimen of aldehyde, and you will also find specimens of natural wines, kindly lent to me by Mr. Denman, in which this change of alcohol by oxidation has taken place. In the year 1848 the late Sir James Simpson, of Edinburgh, discovered that aldehyde would produce anæsthetic sleep when its vapour was inhaled, and I have since submitted it to experiment with the view of testing its action on the living body. I find it is a rapidly intoxicating agent, sharp to the nerves of sense, and acting with greater rapidity than alcohol, and with a less prolonged effect, for it is soluble in water, and is so volatile that it boils at 72° F. It is therefore quickly diffused and quickly eliminated from the body. The action of aldehyde upon the living body has been as yet insufficiently studied. It has a close relation to the narcotic action of alcohol, and the symptoms it produces are so similar I am inclined to believe that the narcotism which follows the administration of alcoholic spirit is partly due to its production.

The presence of acetic acid in wines is on the whole not injurious, if the wine in other respects be free of adulteration. The tendency of this acid itself is to promote the digestion of albuminous foods, and I have sometimes observed in persons, whose digestive power is feeble, signs of improvement under its use. In saying this I do not however wish to convey that therefore a rough acid wine should be taken for indigestion, for the acid in such instances may be administered without the wine and perhaps with greater advantage. I only wish to record that acidity of wine, in which fermentation has ceased, is not a source of additional injury. The astringent acid of some wines—called tannic—has been advanced as useful in the cases of certain persons who suffer from laxity of body and who require astringent remedies. It would be wrong to dispute that there may be in wines a virtue of this kind; but it is not peculiar to wine. It can be secured when it is wanted without wine at all, and in a more certain way. This remark holds equally good in respect to what may be favourably spoken of the saline substances which some wines naturally present. I mean to say that the saline constituents can be administered with more certain and therefore with better effect, independently of wine.

Spirits.

Into the different spirits commonly sold, several substances are introduced which exert more or less of baneful influence on the body that receives them. The addition of amylic alcohol has already been condemned and need not again be mentioned, and I omit intentionally, for the sake of brevity, a great number of other added substances which do not seem to me to be active for evil, though they were possibly better left out of the animal organism. After these are withdrawn there remain many other agents which cannot fairly be omitted from our consideration. There is oil of juniper, and oil of bitter almonds, potassa, alum, nitric acid, oil of vitriol or sulphuric acid, and butyric acid. In even small quantities every one of these agents is injurious to the body if it be taken for any long continued period of time. The oil of juniper is an active diuretic, and thereby is injurious to the excreting power of one of the most important of the vital organs. The oil of bitter almonds contains, unless it be specially purified, hydrocyanic or prussic acid, and exerts then in small and often repeated quantities a prejudicial influence on the nervous functions. Potassa causes a dry and caustic action upon the mucous membrane of the mouth, throat, and stomach, for the production of which action it is actually added systematically, that it may give the peculiar sharpness called "biting the palate."

(*To be continued.*)

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Sale of Food and Drugs Bill.

The consideration of this Bill in Committee was resumed on Thursday at Clause 6, in which some verbal amendments were inserted, and the Clause, as amended, was agreed to. On Clause 7,

Mr. Brown moved to add at the end:—"or, if he shall supply such article from any box or other receptacle which is clearly marked in such a way as to signify that the article is mixed, and is so placed that the purchaser may be able to read what is marked thereon." His object was to remove the necessity of wrapping up small quantities of an article in a paper marked "mixed," as that would entail in the case of small sales over the counter a good deal of unnecessary trouble on the seller.

Mr. Bristowe pointed out that the clause as it stood was very good, and that the amendment, if adopted, would open the door to fraud.

After a short conversation the amendment was negatived.

Mr. Sandford moved the addition of the words,—"and stating the nature of the mixture," with a view that purchasers should know what they were buying.

Mr. Mundella thought the amendment would tend to the manufacture of inferior goods.

Mr. Sclater-Booth also opposed the amendment. No information of value would be given by it to the purchaser, who would know nothing as to the quality of the materials used.

The amendment was negatived.

Clauses 7 and 8 were agreed to. On Clause 9,

Mr. Sandford said one of the grievances complained of to the Committee was the incompetency of the local analysts, and the right hon. gentleman had not tried to remedy this grievance in the Bill. In many small boroughs, also, analysts were appointed on the express understanding that they would not carry out the Act, and some members of the Town Councils were the chief offenders. It would conduce both to economy and efficiency if analysts were appointed by the county, and he therefore proposed that, "in England, the magistrates for each county shall, as soon as possible after the passing of this Act, appoint for each county one or more persons possessing competent knowledge, skill, and experience, as analysts of all articles of food, or drugs sold within such county."

Sir H. Peek protested against the appointment of analysts for the purposes of the Bill, on the ground that analyses would be much more efficiently conducted at the Laboratory at Somerset House than by persons who were selected at haphazard, and for whose skill there was no security. Under the present system great injustice was frequently done.

Mr. Sclater-Booth thought it was unadvisable that all analyses should be conducted at a central establishment like Somerset House, and therefore could not accept the suggestion of the hon. baronet, the member for Mid-Surrey. He defended the action of the boroughs, which he thought were quite as vigilant to prevent adulteration as the counties were.

Mr. Pell coincided in the views of the hon. baronet the member for Mid-Surrey with regard to analysts and to the injustice of the existing system. County or borough magistrates knew very little indeed of the subject. He was a farmer, and would like to have his manure analysed, but he would not ask a country analyst to analyse it.

Mr. Wykeham Martin said that he thought borough magistrates were quite as competent as county magistrates to appoint analysts.

Dr. Playfair said there could be no doubt that many incompetent men had been appointed analysts. Parliament, in laying down the system of analysis, provided no safeguards that the analysts should be competent. Even this Bill contained no proper security that the analysts should be competent. But he would say one word for the analysts who had been appointed under all the difficulties of the present system, and suddenly called upon to make analyses without preparation. Before the Adulteration Act was passed Dr. Hassell made 2,000 analyses of articles and found that 76 per cent. of them were adulterated. Since the Act was passed he had made 17,000 analyses and only 26 per cent. of the articles were found adulterated. Much as we might lament the ignorance on the part of analysts suddenly called upon, as a whole the work had been performed to the satisfaction and for the benefit of the public. He could not support the amendment of the hon. gentleman, because he thought London and large boroughs were quite able to find efficient analysts.

Mr. Hardcastle said if there were a large number of analysts, it was probable that they would all be very inadequately paid; but if there were one superior analyst, they could afford to pay him well for his work. Practically, these analysts were placed in the position of judges, for on their decision rather than on the decision of magistrates rested the question whether or not those persons who were accused of adulteration should be subjected to a penalty. He felt it his duty to support the amendment, although he thought the city of London was competent to appoint its own analyst.

Mr. Evans hoped that some provision would be introduced to avoid for the future such gross injustice as had been inflicted on those tradesmen who through the incompetence of analysts had been groundlessly accused of adulteration. He believed the best course to adopt would be to appoint for the work of analysis a competent authority.

Mr. Alderman Cotton said although the right hon. gentleman the member for the University of Edinburgh might treat the faults of analysts very lightly, their faults might ruin the reputation of innocent tradesmen.

Mr. Cawley said it would be inconsistent with previous legislation to leave the appointment of analysts with the county magistrates, who would have to go to the large towns and cities for the persons to be appointed.

Mr. C. P. Villiers thought there was a great deal to be said in justification of the amendment. It appeared that only 24 boroughs out of 171 had appointed analysts, whereas the county magistrates had appointed analysts in 30 cases out of 54. There must be some reasons why the towns and boroughs did not appoint analysts. At present nothing could be more capricious than the operation of the existing law. It had been two years in operation, yet while in some places the law against adulteration was rigorously enforced, in others no analysts were appointed, and the law became a dead letter. The consequence was that the unscrupulous traders sent their adulterated goods to the latter places, and enormous injury was inflicted on the community. The analysts had been condemned, but had they had a fair trial? They did not exist in sufficient numbers at first, but during the last two years a sufficient number of competent analysts had come forward. The House ought to remember that wherever analysts had been appointed great public advantage had accrued. Nothing could be more ridiculous than the statements sometimes made in the House that there was now no adulteration of food. There never was a time when on sanitary grounds an effective measure was more required. For fifty years such an Act had been demanded, and in 1860 an Act was passed, but no analysts were appointed, because the appointment was placed in the hands of those who took care not to appoint them. The Act of 1872 was passed by something like an accident. The present Bill was in his opinion no improvement on the Act of 1872, because it would diminish the protection of the consumer and offer facilities to the traders who practised adulteration. He hoped that the Committee would receive an assurance that the Bill would not be merely permissive, but that the word "may" in regard to the appointment of an analyst would be changed to "shall appoint an analyst."

Mr. Sclater-Booth thought the right hon. gentleman could have given very little attention to the language of the Bill. The difficulty was to insist on the appointment of analysts, when they were told that a sufficient number of competent persons could not be found. The Bill, however, extended the facilities for the joint appointment of analysts by boroughs and counties. There was, unfortunately, no School of Analytical Chemistry in this country, but in a subsequent clause it would be proposed to refer the analyses in certain cases to the Board of Inland Revenue, the effect of which might be that plenty of competent analysts would be found in a few years. When it was stated that county magistrates might be relied upon to carry out the Act he would remind the Committee that the magistrates of two Midland counties had appointed an analyst who was thoroughly incompetent. There were many difficulties in the way of working the Act in counties, while in several boroughs it was very well worked. The hon. member for Edinburgh had borne testimony to the general diminution of adulteration, and he believed that if powers were given to the Board of Inland Revenue still greater improvements might be made.

Mr. Henley thought it would be very invidious and almost unconstitutional to say that boroughs having Quarter Sessions which were competent to try criminals were not to be trusted to appoint analysts. It appeared that these learned pundits were not infallible, for more than one analyst had made a great mistake which other learned pundits had corrected. He should be sorry to see any change made in the direction of the amendment.

Sir W. Fraser objected to the appointment of an analyst being confided to the London Vestries.

Mr. Cole believed that the Vestries, which included men in all positions in life, would be the very best bodies to make such an appointment. His only objection to the clause was that it was not made compulsory.

The amendment was then withdrawn, and

Mr. Sandford moved the postponement of the clause, expressing his concurrence in the view which had been submitted to the Committee by the hon. member for Mid-Surrey, that it would be more satisfactory that things should be sent up to Somerset House to be analysed.

Mr. Barclay hoped the clause would be postponed. He thought it would be most satisfactory that the analysts at Somerset House should be employed on all occasions, and that their decisions should be final and binding on all the parties.

After some further discussion

Mr. Sclater-Booth observed that the clause was necessary to the carrying out the object which the Government had in view in introducing the Bill.

The amendment was negatived.

Mr. Pell moved an amendment, the effect of which would be, if adopted, to limit the operation of the clause to boroughs containing, "according to the last published census, for the time being, a population of 25,000 and upwards."

Mr. Backhouse supported the amendment.

Mr. Sclater-Booth thought that trivial matters of this character should be left to the discretion of the local authorities, instead of being made the subjects of Acts of Parliament.

After some further conversation, the amendment was withdrawn.

Dr. Playfair moved to insert the words, "Provided that such analysts be not engaged in the trade of buying or selling any article of food or drugs." He thought it was undesirable that men should be appointed to analyse in a public capacity the goods of others with whom they might be competing in trade.

Mr. Cole argued that if chemists and druggists were excluded there would be many localities deprived altogether of the services of an analyst.

Mr. Sclater-Booth approved the intention of the right hon. gentleman, and stated that as a general rule the Local Government Board deprecated the appointment of men engaged in trade, but that in point of fact some of the most competent local analysts were persons so engaged, and, on the whole, he was of opinion that the amendment would operate injuriously.

Mr. W. E. Forster supported the amendment, and Mr. Pease and Cawley opposed it.

Dr. Playfair said the men they wanted were competent professional analysts—not manufacturers.

Colonel Barttelot supported the amendment as an independent member. It was not right that persons who dealt in particular articles should be called in to analyse them. They should appoint men who were properly qualified to do the duty cast on them.

Mr. Wykeham Martin pointed out that in some counties a medical man in private practice was the analyst.

Mr. Sclater-Booth believed that when a sample of an article went to be analysed it was sent marked in cipher, without the analyst knowing from whom it was obtained. Those gentlemen who had already been appointed could not well now be disestablished. Although it might not be a matter on which it could rely, he assured the Committee that he would endeavour to see that proper persons were appointed for those duties.

Sir A. Lusk supported the amendment.

Mr. Cawley suggested that the amendment should be confined to the special trade in which a person might be engaged.

Mr. Sandford also recommended that it should be modified so as only to exclude a man who sold the articles in question within the district for which he was appointed as analyst.

After some conversation the amendment was withdrawn, Mr. Sclater-Booth stating that he would introduce some words on the report to meet the views of the right hon. gentleman.

The Clause as amended then was agreed to, as was also Clause 10.

On Clauses 11 and 12 amendments were proposed by Dr. Cameron and Dr. Playfair. After a brief conversation the first amendment was withdrawn, the second negatived, and the clauses added to the Bill.

Clauses down to Clause 20 having been agreed to,

Progress was reported, and the House resumed.

Conviction under the Pharmacy Act, 1868.

Mr. William Valentine Aldridge, of 8, Islington Green, oil and colourman, was summoned before the magistrate sitting at the Clerkenwell Police Court, on Thursday, May 6, for an offence under the 17th section of the Pharmacy Act, 1868, by having sold a packet of oxalic acid (a poison) without affixing thereto the word poison, the name of the article, and the name and address of the seller.

Mr. Flux appeared on behalf of the Pharmaceutical Society and stated the case.

Mr. Ward deposed that on the 25th March he applied at the shop of the accused for a small quantity of oxalic acid. The shopman took a common piece of paper, made a twist, and then took from a drawer some oxalic acid in his hands and poured it into the paper, screwed it up, and handed it to the witness without label or warning of any sort.

Professor Attfield proved having analysed the contents of the packet, and that they consisted of somewhat impure oxalic acid.

The defendant did not deny the charge, and in answer to the magistrate said that he had been a trader many years, and had sold a large quantity of oxalic acid, chiefly to dyers and shoemakers, but that he gave orders that the name of the article should be written on every packet. He had not intended to infringe any Act of Parliament.

The magistrate said that the statement virtually amounted to a plea of guilty. He was of opinion that there existed necessity for great caution in the sale of such a poisonous substance, because it might get into the hands of a child or other ignorant person, and being in appearance something like crystallized sugar, might be eaten. The law regulating the sale of poisons must be respected, and he should fine the defendant half the full penalty, or 50*s.*, and costs.

Prosecutions under the Adulteration Act.

Charge of Selling Adulterated Scammony.

Mr. Francis Hallam, chemist and druggist, of High Street, Burton-on-Trent, was charged on Tuesday, April 27, before the magistrates sitting at the Burton Police Court with having sold as unadulterated a quantity of adulterated powdered scammony. Mr. Briggs, of Derby, appeared for the defendant. John G. Horder, district inspector under the Adulteration Act, deposed that he purchased a shilling's worth of scammony on February 11 from the defendant, and handed a portion of it to Mr. W. L. Scott, county analyst, for analysis. He told the defendant for what purpose he had purchased it. On

March 5th Mr. Scott forwarded him a certificate which stated that the scammony was adulterated to the extent of 26·98 per cent.—of which nearly 17½ per cent. was flour and the remainder was foreign mineral manner chiefly argillaceous and silicious. It was injurious to health.

Mr. Briggs, in the first place, argued that the analyst himself ought to have been present so that an opportunity would have been afforded of examining him as to his method for detecting adulteration, but he did not press this point. He then proceeded to argue that the argillaceous and siliceous matters were natural impurities contained in the scammony, and that the flour was intermixed in the manipulation of the article, preparatory to sending it to England, in order to prevent the pieces adhering to each other. He quoted several authorities to show that if there were 70 per cent. of the genuine resin present the whole could be considered as unadulterated, and to bear out explanation of the alleged adulterants. He further stated that Mr. Horder had only purchased Aleppo scammony, which was the poorest kind.

The Bench consulted, and Mr. Horder told the magistrates that if they had any doubt about the article being adulterated he would ask them to adjourn the case so that the clerk of the peace for the county, who had ordered the proceedings to be taken might be represented.

The Chairman said they had no doubt about the case at all, as they had decided to dismiss it, believing that the scammony was not adulterated beyond what was natural and necessary.—*Burton Chronicle.*

Poisoning by a Vermin Killer.

An inquest has been held at Boston, Lincolnshire, before Walter Clegg, Esq., coroner, on the body of Kate Jebb, 32 years of age, who died from the effects of poison. The following evidence was adduced :—

Sarah Johnson, a little girl who waited on the deceased, said her mistress sent her to Mr. Lewin's shop about nine o'clock on Saturday evening for a pennyworth of laudanum. She handed the bottle to the deceased, and shortly after saw her take the bottle from her mouth. After this she requested the child to fetch a second pennyworth. The child took the bottle, but instead of going direct to the chemist's again she went home and told her mother what had occurred, and the latter would not let her go the errand on which she was sent. The child retured to the house and told deceased her mother would not let her fetch the laudanum. Deceased then requested her to fetch some vermin killer to poison the rats—a thing she had been talking about all the week. The child on her return gave the packet of poison to the deceased, who told her to lock the door, take the key to a neighbour, and then go home.

Mr. Lewin, chemist, deposed to seeing the last witness come to his shop on Saturday night for a 3*d.* packet of vermin killer. It was his own make, of a light blue colour, and contained strychnine. The witness said there were no restrictions on the sale of vermin killer.

Peter Holland, a young man who lodged in the house, deposed to finding the deceased groaning and retching. He ran at once to fetch Dr. Arthur Tuxford.

John Jebb, husband of the deceased, deposed to her being subject to great excitement at certain periods, and to her being unusually excited on Saturday afternoon and evening. He left her at home a little before nine in the evening. He returned about ten, and finding the door locked went into the town again. On returning a second time a little after eleven he found Dr. Tuxford in the house attending to the deceased, who was very bad. Witness knew no reason for deceased destroying herself.

Dr. Arthur Tuxford deposed that he found the deceased sitting up dressed in bed. She asked why he had come. He told her he had heard she had taken poison, and asked her what she had taken. She replied, "I shall not tell you, because I want to die." She was very excited, her pulse was very rapid, and she had great difficulty in breathing. He immediately administered a powerful emetic, and sent for a stomach pump. She vomited a lot of bluish-looking mixture, and said, "It's too late; you can do me no good; I took that (pointing to some papers on the floor) an hour and a half ago, and oh! do let me die." He applied the pump, and administered a draught of hydrate of chloral, applied hot water to her legs, body, and feet, counter-irritants to her heart, and cold to her spine. Opisthotonos set in a few minutes afterwards and continued till death ensued. Verdict, temporary insanity.—*Stamford Mercury.*

Notes and Queries.

[435]. CEMENT FOR COMPOSITION MORTARS.—I have pleasure in informing "Vinegar," in answer to his query in the *Pharmaceutical Journal*, that I have found the following cement answer the purpose he mentions remarkably well :—

Hydrarg. Subchlor.	
Pulv. Acaciæ	partes æquales.
Mucilaginis	q. s.

C. Ekins, *Bristol.*

Another correspondent writes that Kay's Coaguline will answer the purpose.

[440]. UNFERMENTED GINGER BEER.—"*Good Templar*" asks for a recipe for making Ginger Beer without a machine (unfermented).

THE BOILING OF SULPHURIC ACID.—In a paper recently read before the French Academy of Sciences (*Comptes Rendus*, lxxx. 473), M. Bobierre stated that the ebullition of sulphuric acid may be conducted as regularly as that of water, if a suitable quantity of platinum be introduced with it into the retort. The method adopted by the author is to place in a retort of 580 centimetres' capacity at least 12 grams of platinum foil; then to add 320 cubic centimetres of sulphuric acid, and heat gradually over a gas furnace.

NOTE ON CHLORAL HYDRATE.—M. Oré states (*Journ. de Pharm.*, May, p. 426) that a very small quantity of carbonate of soda is sufficient to remove the acidity of chloral hydrate in solution and to render it alkaline. There is a slight disengagement of carbonic acid and some chloride of sodium is formed. Comparative experiments have shown that whilst chloral hydrate retards the coagulation of blood, chloral hydrate thus rendered alkaline by carbonate of soda entirely prevents it. The addition of the soda does not at all interfere with the anæsthetic properties of the chloral.

The Glasgow Memorial.

Sir,—Our attention has been called to the following statement in to-day's Journal in the letter signed "Assistant," viz.:—

"Who could have imagined anything more ridiculous than that Mr. Frazer went to London with the intention of presenting a memorial without first obtaining a copy of it in Glasgow?" As the parties who had charge of the memorial we cannot allow such a statement to pass unheeded. Mr. Frazer was asked to support the prayer of the memorial at the Council Board, which he agreed to do, but he was never asked to present it. The document was sent by us direct to the Secretary of the Society at Bloomsbury Square, for presentation to the Council, and if we understand forms aright, neither Mr. Frazer nor any other member of Council was entitled to see it until it had been received by the President, and read by him, or, as is usual with official communications, by the clerk or Secretary, in presence of the Council. How a different course has seemingly been adopted in this case our much respected President or Secretary of the Society should be able to explain.

John Currie, Ex-President,
J. M. Fairlie, Secretary,
G. C. and D. A.

Glasgow, May 1, 1875.

Sir,—"Scotus" has misunderstood the purport of my request for his name. The argument "Scotus" gives for me to reply to his personal remarks is just the one I would be disposed to make in favour of "Scotus" signing his name to his communications openly. Your readers must judge who is doing things in the most "tortuous or underhand way," the one who makes an attack in the dark, or the one who is called upon in his official capacity to sign a document, and is prepared to defend his conduct in doing so. I therefore decline correspondence with irresponsible parties.

While writing I may express how sorry I am for his own sake that Mr. Kinninmont should introduce into his letters garbled, and in some cases simply hearsay statements. "Those who live in glass houses should not throw stones;" and I fear your various correspondents are doing this to knock their own heads.

J. M. Fairlie.

Endrich Place, Glasgow,
May 1, 1875.

Sir,—Having passed my Major Examination in Scotland I feel I should like to say a few words respecting the Glasgow memorial. I for one do not think that the examinations prevent young men from remaining in the business. I have heard many young men remark that it is the remuneration and not the examination that they object to, as even when they have passed the Minor the salaries they receive will not allow of their going in for the Major.

As an instance of the salaries which are offered in some places I may mention that when I had passed my Major I tried to obtain a situation in Edinburgh, and was offered 50*l*. a year to manage a business, and live out of the house. You can imagine my disgust at such a proposal, as the money would not have done more than pay for my board and lodging. Instead therefore of trying further in that city I came straight to London, where I got 55*l*. in the house as senior assistant, without any trouble.

As regards the Edinburgh Board of Examiners I am of opinion that a more efficient, straightforward, and upright set of gentlemen never sat as examiners, and I am sure that none but men who have been unluckily plucked will say anything else. When I was up for examination the only grumblers were men who had been up before.

Harry Hyne.

130, *Seymour Place,*
Bryanston Square.

Sir,—We must, of course, accept the declaration of Messrs. Currie and Fairlie, that in the Glasgow memorial no insult is intended to the Edinburgh Board of Examiners. But it is, to say the least, very difficult to reconcile that statement with the words and apparent meaning of the memorial. It appears, moreover, from Mr. Kinninmont's last letter, that these two gentlemen are entirely responsible for the objectionable nature of the words employed in the preamble of the memorial. Nevertheless, I would not be inclined to be too hard on these gentlemen, as they may have a conception of a perfect Board of Examiners "in the dim vista of the future," and, consequently, may be endeavouring their utmost, to bring about that state of Elysium. The memorialists seem to think that the examinations are the cause of the scarcity of assistants. I agree with them in that opinion, but I will give the reason why such is the case. In the first place, we will grant, for sake of argument, that there are plenty of apprentices in the market. Well then, in the natural course of things plenty of assistants will be found; but is the course of things in this trade natural? I emphatically say "no." Young men are told that they have an examination to pass before they can open shop. This examination requires study, without which all is in vain, and for study they require books and time. And now I come to what qualifies my assent to the memorial. The money for the purchase—mere purchase, I say—of books is wanting; the time for study is wanting. Is it natural, I ask, therefore, is it fair, that a young man be asked to give time which he has not for study, and money which he does not possess for the requisite books? What more would be required to complete the utter inability of any young man to pass. But I have assumed that there are plenty of apprentices; now this is not so—at least in the district in which I reside, the South of Scotland—and the scarcity is not confined to the drug trade. I have known employers advertise for three, four, and six months before getting an apprentice, and even then there was no choice. This is owing to the large inducements offered in the shape of long pay and short hours by other trades, which are thinned by emigration. Very soon, however, there must be a change, and masters will have to offer better remuneration and shorter hours of labour. In disposing of the apprentice difficulty—and it seems to me that this is all—I have disposed of the lack of assistants.

With regard to doctors keeping open shop, which hinders profits and consequently higher wages, doubtless this will soon right itself, and the intelligent public will be able to discriminate between the man who seeks to degrade his profession for the purpose of hindering another from rising, and the man who pursues his calling honestly and industriously.

Concerning the Examining Boards as now constituted there is no doubt but that a great improvement has taken place within the last few years, and although there may be room for still more, nevertheless, the system appears to one who has not yet ventured before the examiners, and to outsiders generally, to be as perfect and honest and impartial as possible under the circumstances.

Therefore I sincerely trust that the Council will not give too much weight to the memorial, and if it is discussed, that it will not give effect to the suggestions which seem to me ill-timed and out of place.

In conclusion, I regret that any display of feeling should have entered into the correspondence, as it seems that some have the idea that the Glasgow druggists are in a state of jealousy towards their brethren in the east. We are bound, however, to accept their distinct assurances to the contrary.

A Young Scot.

May 3, 1875.

Sir,—In reference to the scarcity of assistants in Glasgow and West of Scotland being due to the effect of the examinations of the Society upon young men in the trade as represented in the memorial of that city, my views entirely coincide with those communicated to you in the letter of "Ph. C.," and published in the Journal for April 10. Like him, I believe the reasons assigned by the Glasgow chemists are quite erroneous. The most probable explanation of the dearth of assistants, not only in Glasgow but in Edinburgh and other places, is the insufficient recompense for the necessary outlay of time and money, not exclusively for the "Minor," but in order to acquire a fair knowledge of the line of occupation we pursue; and the preference often given to unqualified men, provided they have a prepossessing appearance and accept a lower remuneration than the registered student will demand.

Edinburgh has not so marked a want in that respect, on account of its educational advantages and other facilities, so that many are willing to reside there for a year or two that they may pass their examination and then remove to a place with greater inducements in a pecuniary sense.

As regards the places for conducting the examinations I do not think any change on the present mode of procedure would be conducive to the interests of the Society or the private advantages of the individuals concerned.

Moreover, I believe a Branch was established in Edinburgh for the convenience of "North Britons," and not for the inhabitants of special towns; and what place could be more suitable than Scotia's capital itself, so long renowned for science, art, and literature, leaving Glasgow to continue its famed mercantile pursuits?

Further, I should think Dublin, Erin's capital, has greater claim for a centre than Glasgow has.

J. B. L. M.

The Sale of Vermin Killers.

Sir,—It appears to me somewhat remarkable that both the writer of the article on the sale of vermin killers and your correspondent "A. A." should have overlooked Section V. of the Pharmacy Act Amendment Act, 1869, which enacts that "Schedule (F) of the recited Act is hereby altered by substituting for the second column headed Name of Purchaser, a column headed Name and Address of Purchaser."

I fear that there are many who are only too ready to be guided by the printed poison books without troubling to ascertain if they are quite correct. I do not remember ever having seen a printed "Poison Book" with a column for the address.

With regard to the necessity of registering vermin killers I think there need be no doubt arsenic and strychnine are placed in Schedule A, and we know that these are the poisons generally contained in them.

In conclusion, I would suggest that some of the surplus energy of the Council might quite as appropriately be devoted to this subject as to the consideration of a universal pharmacopœia or any other equally utopian scheme.

I would venture to suggest for their consideration, the advisability of paying the local secretaries a salary, in return for which they should be deputed to see that the Pharmacy Act is properly carried out, and to institute proceedings when necessary. A. P. S.

[*** "A. P. S." is quite correct as to the fact that the registration of the purchaser's address is specifically directed by the Amendment Act he refers to. Our remarks last week were simply directed to showing that according to the original Pharmacy Act this is distinctly necessary.—Ed. Pharm. Journ.]

The Botanical Prize.

Sir,—As the conditions for the botanical prize are again brought before our notice, I take the opportunity of giving you my ideas on the subject. I noticed last year when the prize was awarded that only one collection had been sent in. This is hardly surprising considering the conditions that are laid down for competitors. It is only open to apprentices and associates who must be under twenty-one years of age. Now, as an associate must be over twenty-one, according to present regulations, I fail to see that he is eligible, and, as a rule, apprentices do not commence to study botany, etc., until they are preparing for the Minor; they are necessarily incompetent to make such a collection. To the associate who is preparing for the Major examination, and consequently studying systematic botany, such a collection would be invaluable. Why, therefore, should he be shut out?

A Would-be Competitor.

"Resin of Aloes."

Sir,—In reply to Dr. Tilden's letter contained in your Journal of 24th ult., I beg to state that I regret very much if I have misrepresented his views. Permit me to say, however, that the substance referred to by him as "the soluble, brown, uncrystallizable substance which constitutes a considerable portion of all aloes," and which he asserts "is none other than the changed aloin of Dr. Craig," is not the substance with which I experimented. So far from his view being correct about the identity of the two substances, the changed aloin I employed was originally crystallized aloin, which had afterwards undergone change by exposure to the air in a damp state.

If Dr. Tilden will read again what he said at the Conference in 1870, he will find that in addition to the opinion quoted by him in his letters as "the only expression of opinion to which he had ever committed himself definitely," he uses these words:—"The active constituent of aloes is still unknown;" again, "The purgative property is not due to aloin;" and again in the postscript, "All existing facts point to the conclusion that the various kinds of aloes do not owe their purgative action to the crystallizable aloin they may contain." The opinion, quoted by Dr. Tilden, must be read in the light of what goes before, and certainly I never imagined that he referred to "aloetin" in the opinion he quoted, seeing he had in that very paper from which he quotes described aloetin "as a mixture of anhydrous aloin, which is capable in the presence of water of recovering its crystalline condition and the brown oxidized substance referred to further on."

The reference in these words could not be to the postscript, which had then no existence, and I naturally thought that he referred to the resin, which is "a brown oxidized substance, referred to further on." I knew that he believed that the purgative property was not due to aloin; and I also knew that if all the aloin be extracted from aloes there is no "brown uncrystallizable substance which constitutes a considerable proportion of all aloes," except the resin, left, so far as I am aware, to which he could refer. I adopted this conclusion all the more readily that in 1872 Dr. Tilden, in an able paper, mentions as the "proximate constituents" of aloes only three—1, aloin and products of its decomposition and change; 2, resinoid matter; and 3, accidental ingredients; wisely omitting all mention of "aloetin" as a proximate constituent of aloes.

William Craig.

Edinburgh, May 4, 1875.

Is Saxifragra Tridactylites an Insect-Devouring Plant?

Sir,—The carnivorous proclivities of our British Droseraceæ and Pinguiculeæ have already been noticed in this Journal. These plants, like animals fed on abnormal food, present a different appearance to the "lighter feeding" species; the striking deficiency of (active) chlorophyll and their wan squalid leaves, not relieved as in the Pinguicula, or as in the Drosera somewhat brightened by the thick besetment of viscid red glands, mark them as distinct from ordinary plants. Possibly to these Saxifragra tridactylites may be added. The peculiar clammy feel of the plant, similar to Drosera, first led me to notice it more closely, and I then saw how each plant had one or more dead insects adhering to it. Some dozens of plants have since been submitted to examination, and in almost every instance the *débris* of some insect was attached to the leaves. Viewed under a two-inch objective the glands presented a very similar appearance to those of Drosera and secreted a viscid fluid on being irritated. The leaves compared with other plants are but sparingly supplied with chlorophyll though their slightly green colour is intensified on immersing in hot water. A small midge placed on the leaf had great difficulty in freeing itself from the clammy glands, and at last was held by them.

Experiments are wanting to ascertain if the insects are assimilated by the plant or if it is only a mechanical attachment. If the affirmative be proved it will extend the plant carnivora to another order and from a uliginal to a glareal or rupestral growth. The affinities between the Droseraceæ and Saxifragaceæ would moreover be strengthened by the occurrence of carnivora in both orders.

G. C. Druce.

Northampton.

Suppositories.

Sir,—Having to make two dozen suppositories this morning I thought I would try Mr. A. Ellis's plan, published in a recent Journal, with this modification—viz., using 2-inch squares of waxed paper instead of writing paper, folding them round a wooden mould I always use, and placing them in a dry sand-bath, thus saving both the time and trouble of wetting, inserting in bottle, and re-emptying moulds. Also pouring into the moulds from a small palette knife I consider an improvement.

They turned out a success, having a better appearance and shape than I had previously obtained when using tin foil moulds.

The excipient I use is as follows:—

Benzoated Lard	50 grains
White Wax	20 ,,
Cacao Butter	104 ,,

For twelve suppositories; which answers well both in summer and winter.

Fredk. B. Bingley.

Guildford, April 26, 1875.

In Memoriam.

It was with a shock of intense sorrow that I, in common, I am sure, with hundreds of others, read the announcement of the death of Daniel Hanbury, and I felt impelled to ask you for a few brief lines of space in which to pay a tribute to his memory.

I do not intend to say one word of his scientific attainments, of the loss which the profession has sustained by his death, but to tell the world of workers in the field in which he so diligently laboured something of the man whose loss they deplore.

Conscientious discharge of the duties that came to his hand was the characteristic of his life which cannot be too widely known or too closely imitated. Conscience dictated the path he should follow without swerving to the right or to the left, whether in business matters or in following his scientific studies, and the example he set should be known beyond the circle of those who had the good fortune to be brought into daily contact with him.

Of his widespread and unostentatious charity none but the recipients will ever know, for he was one of those whose left knew not what his right hand gave.

But to his tender regard for the feelings of others numbers are living who can bear witness; while many quondam despairing students must bless the day they first knew Daniel Hanbury. The extreme simplicity and blamelessness of his life will cause his memory and example to be cherished with the profoundest regret, and all who ever knew him must feel that by his death they have lost a valued friend.

Occupied as he was by business he still found time to perform prodigies of labour—now before the world—in those hours so often frittered away; and yet with all his occupations he never ceased to be, with a stern sense of duty, the true-hearted, kindly, gentle man who charmed all brought within the radius of his influence.

In the example of his unswerving sense of duty, his conscientious diligence and his faithfulness to the right, it may most truly be said that "he being dead yet speaketh."

A. C.

Paris, April, 1875.

Aucuba Japonica.—Mr. R. Goodwin Mumbray, of Richmond, writes respecting this plant, which although introduced nearly a century since has only fruited in this country during the past few years, that a medical friend has recently shown him a specimen bearing a large crop of scarlet berries, the size of hazel nuts. As the situation was very unfavourable for the pollen to have been carried to it by the wind, our correspondent thinks the fertilization was probably effected by bees who have conveyed the pollen from male plants situated as far distant as Kew or Wimbledon.

W. Bird.—Dynamite is a mixture of nitro-glycerine and some inert substance, generally a silicious earth. See *Pharm. Journ.*, Jan. 18, 1873, p. 563.

"*Minor.*"—We do not know of the existence of any such book.

"*Oxygen.*"—You are recommended to consult a dictionary as to the meaning of the word "anonymous."

E. J. B. We are not acquainted with any work of Lindley's, bearing the title you mention, which describes British plants. Babington's 'Manual,' and Bentham's 'Handbook' are the two most generally used for the purpose.

"*Competitor.*"—(1) Specimens of any trees included in Babington's 'Manual' are admissible. (2) Yes.

G. C. Druce.—(1) *Viola sylvatica*, var. *Riviniana.* (2) *Carex præcox.* (3) *Trifolium repens.*

S. C.—We presume you mean sarcosin, a substance formed by boiling creatin with baryta water. Its formula is $C_3H_7NO_2$. It is also a derivative of acetic acid. For a history of the same see Watts's 'Dictionary of Chemistry,' vol. v., p. 197.

W. Thomas.—We are unable to furnish any information respecting "those men who undertake to get one through the examinations."

Strychnia.—The change is probably due to the decomposition of the strychnia.

"*Stamp.*"—Your letter has been received, but the labels referred to in it were not enclosed.

Erratum.—On p. 882, col. i, line 38, *for* Mr E. Hefford *read* Mr. C. Hefford.

"*Plato.*"—We have no recollection of the appearance of any such paper.

"*Good Templar.*"—The published formulæ for inks and tooth powders and pastes are innumerable, and may be found in any good book of recipes. The other information you ask for we will endeavour to obtain.

R. Calvert.—You may obtain all necessary information by applying at the Patent Office.

N. M. Goose.—First put as much distilled water as you have oil to emulsify into and let it well moisten the sides of the bottle. Next add the oil and shake well. Then add the potash gradually and more water, shaking constantly till the whole has been added. The oil should be as fresh as possible and the potash free from carbonate. The proportion of the potash to that of the oil is scarcely sufficient to yield a very good result.]

F. Porter Smith.—Probably silica.

G. Taylor.—'The Handbook of British Plants,' by Lowndes Notcutt, published at 171, Fleet Street.

"*An Examined A.P.S. (Glasgow).*"—We cannot make our columns a medium for the communication of threats of personal violence. In other respects while the letter of our correspondent on the subject of the Glasgow memorial appears open to the reproach of being "scurrilous and malicious" its composition and spelling are not creditable to the author or to the fact of his having been examined.

J. B. L. M.—(1) It is the custom in London when "Ext. Aloës Aquasum" is ordered, to use Ext. Aloës Socotrin. B.P. When "Extractum Aloës" is ordered, the same should be used, because in the P. L., 1851, only the Extract of Socotrine Aloes was official, and it was there simply called "Extractum Aloës." (2) It is a name sometimes given to Syrup of White Poppies. (3) Oxide of Zinc officially described as "a soft, nearly white, tasteless, and inodorous powder, becoming pale yellow when heated." (4) We prefer to follow the orthography of the Pharmacopœia.

Communications, Letters, etc., have been received from Mr. Barrett, Mr. J. McCann, Mr. Wilkinson, Secretary of the Assistants' Section of the Glasgow Chemists and Druggists' Association, Secretary of the Bristol Pharmaceutical Association, A. P. S., "Dix Vera," "A Minor," "Pharmaceutist."

NOTES ON BRAZILIAN DRUGS.

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

In this country very little is known of the drugs used in Brazil, although there are probably some to be found among them possessing considerable medicinal activity. In the catalogue of Brazilian drugs by Martius,* a number are enumerated and the medicinal virtues of many of them are described, but no description is given of the characters by which one drug may be distinguished from another. In different countries of South America the same name is applied to different drugs, if they possess somewhat similar properties; hence much confusion arises. Thus the jaborandi of Pernambuco is a Rutaceous plant, while the jaborandi of Paraguay is a species of *Piper*. On this account it is necessary that the physical characters of the drugs from the different provinces should be described, so that in case any of them are hereafter imported into this country there may be no difficulty in recognizing the particular kind required.

The following list is a description of some drugs lately presented to the museum of the Pharmaceutical Society by Messrs. Cyriax and Farries; the specimens were collected in the province of Rio, in Southern Brazil. For convenience of reference they are arranged in alphabetical order according to their native names. The specimens were accompanied by a manuscript list, drawn up by Dr. G. S. Barnsley, together with remarks upon the medicinal properties of the various drugs. Most of these appear to have been copied from Martius's work; only his original statements will be noticed.

Braço do Preguiça or *Velame*. This drug consists of large brittle leaves of a papery texture. They are, as far as can be judged from their broken state, about a foot long and nine inches broad, of a dark-green colour above, and white and hoary underneath. The hoariness is owing to the under side of the leaf being densely covered with stellate hairs which are almost entirely absent on the upper surface of the leaf. The veins are depressed on the upper side of the leaf and prominent beneath. The stalks and petiole are also densely covered with a thick coat of down, and with a number of linear brownish scales like those on the base of the fronds of ferns. The plant is referred by Dr. Barnsley to *Solanum jubatum*, Dumal. The leaves correspond exactly to specimens of that species in the British Museum. An entire leaf, however, sent with the drug, which is without scales on the petioles, is referable rather to *Solanum bullatum*, Vell. In the collection of the late Dr. Pereira the same drug occurs under the name of "Panacea," but from the fragmentary state of the leaves it is impossible to say to which of these two species it may belong. According to Dr. Barnsley, the leaves and root are used in the form of infusion or extract, and are considered to possess excellent antisyphilitic properties; they are also sometimes used as a purge.

According to Martius, Braço do Preguiça is used as a resolvent in congestion of the bowels and as an external application for cleansing and healing wounds and ulcers.

Bútua.—This root corresponds in structure and taste with true Pareira Brava root, but is of a more yellowish hue than is usual in that drug. A smaller piece, labelled "abutua negra," exactly corresponds with the usual specimens of true Pareira Brava met with in commerce, and is without doubt the root of *Chondodendron tomentosum*, R. et P. Dr. Barnsley states that it is used in the form of infusion, extract, and powder in chronic hepatitis, dyspepsia, etc. He makes one extraordinary statement with regard to this drug, for which I am totally unable to account:—"This root has a basic salt which unites with sulphuric acid, is white, etc., almost like that of cinchona. It is exported to Europe in great quantities to adulterate quinine." This salt has been examined by Mr. J. Moss, F.C.S., and proves to be sulphate of quinidine!

Caroba.—"This specimen consists of the leaves of two nearly allied plants, one of which has serrate and the other entire leaflets. The serrate-leaved species is known as 'Caroba paulistana,' and the one with entire leaves as 'Carobinha' or 'Carabo da muida.' The Carobinha consists of bipinnate leaves from 12—18 inches long, with 7—10 pair of pinnæ, each pinna having about eight pair of leaflets and an odd one; the leaflets are obovate, slightly unequal sided, sessile, but tapering below; the leaflets in size and texture resemble the leaves of *Chimaphila umbellata*. The margin of the leaves is entire, and the leaves are smooth on both sides and minutely dotted beneath, but the dots are not transparent. The petiole is slightly winged on its upper surface so as to appear canaliculate, and the rachis of the pinnæ is also slightly but more distinctly winged. The leaves appear to correspond well with those of *Jacaranda oxyphylla*, Cham."

The Caroba paulistana has leaves and leaflets similar to those just described; but the leaflets are serrate about the middle of the leaf and tapering at both ends, and minute hairs are sparingly scattered over the leaf. It seems to correspond well with the description given of *Jacaranda paulistana* in De Candolle's Prodromus. Martius gives this name as synonymous with *Jacaranda oxyphylla*, Cham., of which it may, perhaps, be only a variety. The leaves of both species have a distinctly bitter taste.

According to Martius, other species are also used under the name of Caroba. Among these are *J. procera*, Spreng., which has leaves abruptly pinnate with the pinnæ imparipinnate, and the leaflets elliptical, wedge-shaped, and obtuse; *J. subrhombea*, D.C., which has bipinnate leaves with both leaves and pinnæ imparipinnate, the leaves having not more than four pair of pinnæ, and the pinnæ not more than five pair of leaflets; *J. Caroba*, which has abruptly bipinnate leaves, with not more than four pair of imparipinnate pinnæ, and the pinnæ with not more than six pair of leaflets, which in this species are elliptical and serrate.

From the leaves are prepared an infusion, a decoction, and a fomentation, which are used in syphilis and skin diseases arising from it, in which, according to Dr. Barnsley, its effects are most marked. He states that it is a favourite remedy in Brazil.

Casca d'Anta.—This is a thick yellowish-white bark. Both the inner and the outer surfaces are smooth. When cut transversely the substance of the bark is seen to be made up of numerous resinous granules, the outer layer being very thin and stratified, of a purplish colour, infiltrated with yellowish powder (whether this powder be natural

* 'Systema Materiæ Medicæ Vegetabilis Brasiliensis.' Leipsic, 1843.

or of a fungous nature, I am unable to judge from the small piece received). The taste is bitter and slightly pungent. Dr. Barnsley attributes it to *Drimys granatensis*, Linn., which is certainly not correct, the bark of that tree being of a dark reddish-brown colour and its inner surface very rough. An infusion and a tincture of Casca d'Anta, according to Dr. Barnsley, are used in dyspepsia, debility, leucorrhœa, etc. He further remarks that it is a very valuable tonic, and that he prefers it to quassia or cinchona bark; that it is very abundant, and that the tree grows to an enormous size.

Cipó sumá.—This root occurs in pieces of a pale greyish-brown colour and of a very dense and horny substance, so much so that it is very difficult to cut. The pieces vary in thickness from that of the thumb to that of an ordinary lead pencil. The external surface is much wrinkled longitudinally and covered with numerous warts. A transverse section shows that the meditullium occupies nearly the whole of the root, is of a yellowish white colour, and is marked with a number of horny-looking undulating lines and innumerable horny dots. Under a lens each dot is seen to enclose a bundle of porous vessels. The bark of the root is scarcely distinguishable, except as a dark line at the circumference of the root. The taste is like that of a raw potato, but has a peculiar acridity like that of senega. Mixed with this root are a number of pieces of the stem of some species of *Aristolochia* of the same colour externally, but internally distinguished by having a large porous meditullium with distinct medullary rays, and by the outer bark being of loose texture, dark grey in colour, and about a line in thickness, the medullary rays running through it. It has a slight acridity only. Cipó sumá is referred by Dr. Barnsley to *Anchietea salutaris*, St. Hil., a Violaceous plant. He has probably followed Martius in this. Martius, however, only attributes the Sipó sumá of S. Paulo and Minas Geraes, not that of Rio Janeiro, to the above-named plant. A piece of the plant accompanying the root is certainly not *Anchietea salutaris*, since it has opposite leaves. As the specimen has neither flowers nor fruit it is not possible to identify it.

A FEW NOTES FROM THE FAR EAST ON OPIUM.

BY T. H. BATEMAN, PH.C.

Some of the details in the following notes will doubtless be familiar to most readers, especially to those who take an interest in the manner dwellers in the far east use the drug. Opium has been used as a medicine from the earliest ages, but the date of its being resorted to as a luxury is somewhat doubtful, though it is not at all improbable that it was coëval with its employment in medicine. As connected with a national vice it was not known until the spread of Islamism, when wine and fermented liquors being prohibited, in accordance with the teaching of the prophet, it came to be used in their stead together with bhang, coffee, and tobacco. The inhabitants of the Eastern Archipelago most probably imbibed their predilection for opium from the Arabs, although the particular manner of using it has been derived from the Chinese.

Notwithstanding that the consumption of opium in China is considerable, I think the number of debauchees would compare favourably with the number of drunkards in other countries. From my own observations I feel convinced that in a climate like that of China the drug in some form or other is a necessity. In the summer months diarrhœa and cholera are rife in the crowded, filthy, and ill-drained cities, and I have been frequently informed by the Chinese that a few whiffs from an opium pipe quickly dispel the sharp attacks of pain to which they are subject. In my occasional walks through Shanghae and its environs I have failed to discover (as described by one or two highly coloured articles found in the pages of some English monthly serials) groups of emaciated wretches lying or sitting about the doors of the opium shops. The consumption of the drug in China is large; but then the inhabitants are countless myriads, numbers of whom use the opium pipe as we do the tobacco pipe, namely, as a solace. Would it not be more desirable if the "quasi-philanthrophy" at present engaged in "worrying up" the "opium trade in China" would expend some of its superfluous energies at home? Surely, the neighbourhoods of St. Giles, Whitechapel, and similar dens of vice in every form, afford ample scope. "Ea sub oculis posita negligimus: proximorum incuriosi, longinqua sectamur."

The great bulk of Indian opium finds its way to China, but a few thousand chests meet with a ready market in the Straits Settlements. The mode in which opium sales are conducted in this port (Shanghai) and the manner in which it is stored is as follows:—On arrival it is received by some of the officers of the storage ships and placed on board, being held to the order of the various owners. Patna opium being prepared under the supervision of the British Government it is never deemed necessary by the native brokers to cut or sample it. The price being settled between the merchant and buyer, the vendor gives an order to deliver the number of chests as arranged; this order, being duly stamped by the Customs authorities, is presented to the official in charge of the receiving ship, and the drug is handed over without any further ceremony.

Malwa opium, however, is treated very differently. An order to inspect so many chests is presented with the price attached thereto; should the quality meet the approval of the purchaser, and the bargain be concluded, each chest is opened and three balls are chosen by the broker or buyer, as the case may be, and from each ball one-third is cut as a sample; these cuttings are then boiled down to test the quality more fully, and to prove to what extent adulteration has taken place. It is by no means uncommon to find sand added to increase the weight, in some instances to so great an extent that buyers refuse to take the opium, and cancel their bargain. After the cutting and weighing is completed it is again repacked, and the net weight marked on each chest, and as a further safeguard to the new owners a strip of paper, on which is printed the Chinese firm's name, is pasted on the top and bottom of each end of the chest. It is now ready for delivery, and is taken away in large or small quantities, as may be most convenient, subject always, however, to the pleasure of the Maritime Customs.

The amount of opium cultivated in China is small compared to that imported, but the native drug cannot be smoked without previous admixture with the foreign, as it causes some affection of the skin the nature of which is unknown to me. Frequent edicts are issued from the throne against its culture on pain of forfeiture of land, and imprisonment. This difficulty is overcome by a little judicious "palm greasing" to the local mandarins. I have by me at present a specimen of the native drug from the Szechuan Province. Its external appearance presents none of the characteristics of either Malwa or Patna opium, it being hard, somewhat brittle, and without "odour." In fact, it closely resembles a specimen of opium from Gipps' Land which I had the opportunity of examining whilst at 338, Oxford Street. The average yield of morphia in native opium is 1·5 per cent., although some authorities (!!) state the yield to be 6 or even 8 per cent.; a sample containing such a percentage as the latter has never unfortunately fallen into my hands.

2, *Nankin Road, Shanghai,*
March 25, 1875.

THE OCCURRENCE OF ORGANIC FORMS IN CONNECTION WITH CONTAGIOUS AND INFECTIVE DISEASES.*

BY J. BURDON SANDERSON, M.D., V.P.R.S.,
Jodrell Professor of Physiology in University College, etc.

LECTURE III.

(*Concluded from page* 870.)

Another reason why no method based on the separation of the living contagious particles could possibly be successful is, that the particles themselves, if removed from the conditions adapted to them, would in all probability, as a direct consequence of that change, entirely alter their properties. Even organisms much higher in the scale, for example, many plants containing active principles, become inert when removed from an appropriate to an inappropriate soil. Much more, therefore, should we expect a similar result in the case of organisms, the vital processes of which are so much more under the influence of conditions.

Considering these difficulties, I set myself last year to consider whether there might not be methods of investigation within reach, which, if they did not come up to the strict requirements of the problem, might help us to approach it. If, it occurred to me, in any disease capable of propagation by the insertion of a contagium containing recognizable living organisms, however minute, it were in our power to observe the behaviour of these organisms during and after the act of infection, even if it were impossible to separate them from the contagious liquid or substance along with which they were introduced into the body of the infected person or animal, we should be able, by comparing the transformations or other manifestations of vital activity in the lower organism or parasite, with the functional derangements and textural changes in the higher organism resulting from the infection, to ascertain with the utmost precision the nature of the relation, if any, between the two series of phenomena. If this method could be carried out, I thought it might be anticipated with great certainty that it would be possible by means of it to determine in the particular case, that the one process is or is not the efficient cause of the other.

As regards many infective or contagious diseases, the application of such a method would be impossible, for we have no sufficient knowledge either of the door by which the contagium enters, or of its whereabouts in the organism after its entrance. In the case of small-pox these difficulties do not exist; and of all human contagious diseases it is theoretically the most fitting for such an inquiry. We have the virus, we have the organism, we have the process. We know how the virus enters. We know how it is scattered over the surface as thistle down is scattered over a field; and how each seed sown serves as a centre of origin for a morbid process, complete in itself. If we could—imitating Dr. Weigert's method, but carrying it out much further than he did—not merely search for our organisms at the sixth day, but at each successive period in the local process, from the first sign of functional disturbance in the rete Malpighii at the seat of the future papule, to the maturation of the pustule, and could trace the two developments—that of plant-life on the one hand, and that of pathological and structural change on the other—going on side by side; and, as has been already explained, see that both were correlative manifestations of the same action, the object would, as regards small-pox, be accomplished.

But here we are met by an insurmountable practical difficulty. No opportunity is ever likely to be afforded us of investigating the pathological anatomy of small-pox in those early stages about which it is most important to obtain information. Happily, comparative pathology affords us a means of circumventing this difficulty. In the sheep there is a disease which, as regards its origin, progress, and local manifestations, is the very counterpart of human small-pox.

The virus of sheep-pox, as I had the opportunity of observing in 1869, contains organisms similar to those of small-pox and vaccine. The analogy, therefore, is complete—so complete, indeed, that whatever can be ascertained by observation as to the behaviour of the organism of sheep-pox within the body of the infected animals, might be applied with the greatest confidence to the elucidation of the corresponding processes in human disease. On these grounds, I suggested to the Chief of the Medical Department of the Government that my colleague at the Brown Institution, Dr. Klein, should be requested to undertake an anatomical investigation of the disease, for which I was enabled to obtain material through the kindness of Professor Chauveau, of Lyons, and Professor Cohn. The results have been already communicated to the Royal Society, and will shortly be published in the *Philosophical Transactions,* as well as in the forthcoming Report of the Medical Officer of the Government.

Before giving a short account of them, I must refer for a moment to well known facts relating to the development of the pustule in human small-pox. Each pustule must be regarded as what is called in pathology a focus of inflammation—an acute process which has a centre of origin. Where is this centre? If we refer to a diagram of the skin, as to a map, we fix the first localization of the process at the junction-line between corium and epithelium, *i.e.*, between the structure called the rete Malpighii, and the very vascular layer beneath it which forms the papillæ. Let us consider what lies on each side of that line. Above it there are small cells, polygonal and closely packed—the growing cells of the epithelium. As you trace the stratum upwards, they flatten, then suddenly change their character and become horny. This we call the natural *stratum corneum.* Below the line referred to, there are papillæ composed of a dense but transparent tissue, so closely packed with loops of capillaries that, when these are distended, it looks as if it were all blood-vessels. Below this is a layer where there are fewer vessels, but they are still very numerous.

The anatomical changes in the structures of the corium and epidermis which result in the formation of the small-pox pustule have their principal seat and origin on either side of the well-defined line, which, as I have just said, separates in a vertical section of skin the rete Malpighii from the vascular tissue of the papillæ. Above that line, the pathological processes consist at first merely in overgrowth—*i.e.*, in germination of the cells of the deep layer of the epidermis; but, as it progresses, two remarkable changes occur. Cavities (the future "vesicles" or "cells") form in the Malpighian layer, which are at first full of clear liquid, afterwards of pus; and, secondly, the epidermis-elements appear to fuse together into a horny material.

---

* Lecture delivered at Owens College, Manchester; reprinted from the *British Medical Journal.*

This horny material constitutes not only the covering of the vesicles, but the septa by which the adjoining cells are separated from each other; and it is by the shrinking which attends its formation that the central depression afterwards observed is produced. In the corium, on the other hand, the lymphatic spaces fill, the tissue swells, and thus the prominence or "papule" is formed.

In sheep-pox, the same changes take place; but they have been much more completely studied, as I have said, by Dr. Klein. To save time, I must carefully avoid all that, however interesting, is not essential. Let me draw your attention once more to the rete Malpighii and to the superficial lymphatics of the cutis. In the rete, there is at first a general germination. Then certain cells become distinguished as being larger; these expand by vacuolation; they become cysts. The cysts coalesce, and thus are formed cavities (the cells of the older pathologists) in the thickened rete. In the corium, we have filling out of the tissue by liquid, which occupied the interfasicular spaces of the lymphatic network. Then (tracing the process further) we observe that, in the rete, the vesicles continue to enlarge, and their contents alter. Instead of containing clear liquid with granules, they are full of pus-corpuscles. In the corium, the change is of the same nature, but goes on earlier; the whole tissue becomes inundated with leucocytes.* This inundation begins from the lymphatics, the appearances being such as to suggest an obstruction or blocking up of these vessels. Rapidly the tissue of the corium becomes fuller and fuller of corpuscles, the final act being the extension of the cellular inundation to the rete Malpighii. How do they get there? They are certainly not formed in the vesicular cavities. Dr. Klein has no doubt that they migrate into the vesicles from the papillary layer below, by virtue of their amœboid movements.

As yet I have said nothing about the organisms. It will be remembered that Dr. Weigert found them only in the early stage of the pustule of small-pox; so here it would be in vain to look for them in the stage of suppuration. With this consideration in mind, Dr. Klein devoted his whole attention to the early changes. I may as well state at once that the anticipation that the early stages of the papule would be accompanied by the development of vegetation has been realized. The process has been studied both in the primary inoculation-pustules and in the general eruption, with results which may be thus stated. From the first, the cavities in which liquid collects, whether the lymphatics of the corium or the vesicular cavities of the skin, begin to show indications of containing organic forms. As the process is observed in sections made at various stages, its nature becomes more and more manifest. At first, it might be said, "Oh, these are merely the ordinary septic organisms with which we are familiar." Soon, however, this becomes impossible. First, the form which is most characteristic—that of the *rod*—is entirely absent. Secondly, the stage of the process is not that at which ordinary septic bacteria present themselves. In all infective inflammations, when they assume the destructive character, bacteria may appear in the inflammation-products, but they never appear in the early stages of the process.

Then, finally, the development of the vegetations, whether it was examined in the primary pustules or those of the general eruption, whether in the corium or epidermis, presented everywhere the same characteristics—characteristics which differed entirely from anything we have up to this moment had under our consideration. It consisted in the formation of a felt-work of extremely delicate filaments, which, although they were not jointed, were unquestionably branched, and gave off at the growing ends minute acrospores or conidia, after the manner of the fungi of the penicillium group. These mycelia were first discovered in the initial stage of the disease in the lymphatics. Although the most scrupulous precautions were used—the portions of skin examined being plunged in the absolutely fresh state into alcohol—the fact was so strange, so unexpected, that it could hardly be credited. Whatever doubt, however, existed, was at once removed when it was found that the development was repeated in the "cells" or vesicular cavities of the epidermis, the same forms exactly presenting themselves; and the intimate relation of the whole process to the disease was rendered still more certain when it was observed that, on the appearance of the secondary eruption at the tenth day after inoculation, each of the small papules was an epitome of the large one, not only as regards the structural changes, but also as regards the evolution of plant life which was associated with it.

* From an abstract just received of Dr. Weigert's further researches on small-pox, it appears that the migration of leucocytes takes place in the pustule of this disease in the same way as above discussed in sheep-pox.

NOTE ON ARICINE.*

BY DAVID HOWARD.

Dr. Hesse, in his paper on the cinchona alkaloids, in the *Annalen der Chemie und Pharmacie*, clxvi, f. 259, a translation of which is published in the *Pharmaceutical Journal*, vol. iv., 750, calls attention to the very unsatisfactory state of our knowledge of aricine, the very existence of which he is inclined to doubt.

At the time when Pelletier (*J. Pharm.*, 1829, f. 565), Manzini (*ibid.*, 1842, f. 95), and Winkler (*Repert. Pharm.* [2], xxxi., 294; xlii, 25, 231-3, [3], 1, 11) wrote on the subject, the barks containing aricine appear to have been plentiful in commerce; but the importers, finding them utterly valueless, have never, as far as I can learn, repeated the experiment of importing them, and thus, unfortunately for science, it is impossible to obtain a sufficient supply of the bark to make a satisfactory investigation of the alkaloid.

It seemed, however, so desirable to obtain some fresh light on the subject, that although the quantity of the aricine-yielding bark, *Cinchona Pelletieriana* (Wedd), which still remained in the collection of my uncle, J. E. Howard, F.R.S., was too small to give much hope of a sufficient supply of alkaloid for a full investigation, he placed a large portion of it at my disposal, and I have carefully examined it; and though I am unable to decide the composition and properties of the alkaloid contained in it, I can at any rate say with considerable certainty that it is perfectly distinct from any other of the cinchona alkaloids.

The bark yields a large quantity of quinic acid, differing in no respect from that of the other cinchonæ, and a small quantity of quinovine, undistinguishable from that already known, yielding quinovic acid by treatment with hydrochloric acid gas; but I failed to obtain any trace of cinchotannic acid or cinchona-red. It also contains an intensely yellow colouring matter, little soluble in water, but freely soluble in spirit, to which it gives a beautiful green fluorescence.

The study of the alkaloid presents special difficulties; solutions of the crude alkaloid change very rapidly when exposed to the air, the colour speedily deepening from pale yellow to dark brown, and the quantity of material at my disposal did not enable me to complete the purification. But when the alkaloid was obtained approximately pure, all the distinguishing reagents for the well-known cinchona alkaloids were carefully applied, and proved it to be different from any of them. It is scarcely possible that any impurity should have so masked their properties as to prevent their being recognized, if present. The alkaloid is freely soluble in ether; solutions of its salts give no sign of crystalline precipitate on the addition of sodio-potassic tartrate. The iodide is moderately soluble

* Read before the Chemical Society; from the *Journal of the Chemical Society*, April, 1875.

in water, and will not crystallize either from aqueous or from spirituous solutions. The sulphocyanate is very slightly soluble in water, and the solution does not yield any alkaloid crystallizable from ether; the platinum salt also dissolves with difficulty in water. We may therefore pretty confidently assert that neither quinine, quinidine, cinchonidine, cinchonine, nor quinamine is present, while the constitution of the platinum salt, of which I shall speak below, and the property possessed by the pure alkaloid of crystallizing from ether, sufficiently distinguish it from quinicine or cinchonicine, and the amorphous alkaloid usually contained in cinchona bark.

On the other hand, the gelatinization of the solution of the sulphate, described by Pelletier, is very well marked, even in dilute solutions, but I failed to obtain the sulphate crystallized from spirit that he describes. The addition of nitric acid, or of a nitrate, throws down a yellow precipitate from solutions of these salts; this may be owing to the presence of paricine.

A small quantity of the pure alkaloid, prepared by my uncle in 1847, which he had preserved, gives me the opportunity of adding an observation of the optical properties, which are also distinctive. A solution in alcohol of 90 per cent. showed a specific rotatory power of 63° for the yellow ray.

A portion of this alkaloid gave a platinum salt, which lost 4·63 per cent of water at 105°, it then gave on ignition 13·88 per cent. of platinum; some of my own preparation precipitated cold by platinum chloride from a solution in hydrochloric acid, gave a salt, which, when dried at 100°, gave 13·93 per cent. of platinum; to another portion the platinum chloride was added when the solution was boiling; it showed signs of decomposition, and a considerable quantity of a resinous precipitate separated, and after filtration a salt was deposited on cooling, which gave, dried at 100°, 16·16 per cent. of platinum. This last number most nearly agrees with the percentage 16·31 given by Manzini for the platinum salt of cinchovatine.

The wide divergence of these results from those given by the platinum salts of quinine and its congeners is very remarkable, and points to an altogether different constitution of the salt, strongly confirming the opinion that the alkaloid is distinct. It is hardly to be doubted that the authors who have already described this body are right in taking this view.

The properties of the alkaloid, as well as the composition of the platinum salt, tend to show that it belongs to the interesting, but comparatively little known group of alkaloids comprising paricine and berberine, and it is most probable that more than one is contained in the aricine barks.

SULPHOVINATE OF QUININE FOR HYPODERMIC SOLUTIONS.*

BY DR. P. JAILLARD.

The author, after alluding to the limitation in the practice of administering quinine hypodermically in consequence of the inconveniences sometimes arising from the slight solubility of the salts usually employed, states that this difficulty may be entirely avoided by the use of either an acid or neutral sulphovinate of quinine.

The acid sulphovinate of quinine, which has been described by Schlagdenhauffen,† is white, difficultly crystallizable, and very hygroscopic. It is rapidly altered by heat, and contains only 56·25 per cent. of quinine. It is obtained by the reaction between 54·8 parts of acid sulphate of quinine, and 42·3 of sulphovinate of baryta, both salts being previously dissolved in distilled water. The liquid is filtered to separate sulphate of baryta, and then gently concentrated by means of a water-bath.

The neutral sulphovinate of quinine is, however, the salt specially recommended by the author; it being non-hygroscopic and slightly alkaline, and containing a larger proportion of quinine, viz., 72·16 per cent. It is white, solid, and crystallizes in silky non-deliquescent tufts. It is very soluble in water and in alcohol, and is insoluble in ether.

An aqueous solution of the neutral sulphovinate prepared with 1 part of sulphovinate, and 2 parts of distilled water keeps perfectly at an ordinary temperature. It does not exhibit the fluorescence of the solution of the sulphate; it has a bitter taste, and perceptibly blues red litmus paper.

The neutral sulphovinate can be prepared by adding 8·71 grams of ordinary sulphate of quinine to a boiling solution of 4·27 grams of sulphovinate of baryta in 100 cubic centimetres of distilled water. After boiling some time the whole is thrown upon a filter, and the clear liquor is tested to ensure that the double decomposition has been complete. If the examination should demonstrate that either of the salts is in excess it is indispensable that such excess should be decomposed by the careful addition of a sufficient quantity of the other salt. The solution is afterwards evaporated by the aid of a water-bath until it is reduced to an oily liquid, which upon cooling forms a crystalline mass. This should be dried either by submitting it to pressure, or by placing it under a glass over quicklime, before reducing it to powder. This salt may be used in the preparation of hypodermic injections, as follows:—

Neutral Sulphovinate of Quinine . .	1 gram.
Distilled Water	2 „

Dissolve with the aid of a gentle heat.

Sulphovinate of soda may be used instead of sulphovinate of baryta in the preparation of this salt, operating in the presence of alcohol. But the product thus obtained is not so soluble as the former, and requires for its solution four parts of water instead of two.

PHARMACY IN ITS RELATIONS WITH MODERN MEDICINE.*

BY WILLIAM H. SPENCER, M.B. CANTAB., F.L.S.

The title of a discourse, whether written or spoken, generally serves one or other of two purposes. It serves either to give information or to raise expectation. In the former case the title is in the nature of a guide to an intending reader or listener; the trouble of reading or listening may be avoided if the purport of the discourse be distasteful, or if it seems likely to be dull. In the latter case the reader or listener is placed in a dilemma; he must wade through or listen to the whole of the discourse before he can tell what it is all about, or on the other hand he must leave it alone altogether with the feeling that he may have missed something that would have pleased him.

I am afraid that the title I have affixed to my discourse may have placed some of you who have come to listen to me to-night in the position of the listener in a dilemma. Nor do I well know how to make amends for this. I am afraid I must ask you to hear me through and then find out what it has all been about, settling whether the whole thing has been insufferably dull or satisfactory. But at least I will try to help you to follow me as I go along by giving at the outset a brief outline of the argument of my discourse.

I suppose it would be taken as a matter of course that there should exist relations, and most important and intimate relations, between medicine and pharmacy. But unanimity would probably vanish directly the attempt was made to substitute for vague assertion of general relationship any specific and definite relations, and there would be still greater difference of opinion as to the

* Read before the Bristol Pharmaceutical Association, March 25, 1875.

degree of importance of particular relations. This diversity arises, I think, chiefly from two causes. First, a universal tendency to identify the scope and limits of any department of practice with the interests of those who practise it, or of those on whose account it is practised. Medicine and pharmacy both, in various degrees and at different epochs in their history, illustrate the operation of this cause. The kind of relations that such a way of looking at the matter creates between two related arts may be termed "sociological" and "commercial." Whether men associate for duty or interest, or dissociate for similar reasons, so long as the necessity or preference exists for such relations so long will they be of prime interest and importance both to medical practitioners and pharmacists. The error that is liable to attach to this view is the mistaking those exigencies of practice that arise out of men's association for the conditions imposed on the cultivation and practice of our art by the state of knowledge of the art itself. I may observe in passing that there has been no greater obstacle to the growth and development of arts than this mistake.

A second cause of the diversity of opinion as to what are the particular relations between medicine and pharmacy and what the degree of their importance may be, is to be found, I think, in misapprehension or ignorance of what an art really is—and more especially what constitutes a scientific art. And if there be this misapprehension or ignorance, the conception of an art is pretty sure to take the shape of the particular interests of the persons who practise it. Now, practice of any kind implies an end or purpose, and this purpose is the satisfying a need. In the absence of distinct conceptions of what the needs are which govern the purpose of an art, these needs are sure to become the individual needs of him who practises it. Men need houses in which to live in comfort and safety, and to supply this need is, or ought to be, the purpose of the builder's art.

If, as I am afraid is too often the case, the comfort, to say nothing of other more important needs of mankind, should be set aside for the interests of the builder himself and other trades with which he is connected, then we should have an illustration of the misapprehension of which I speak.

I reject all relations that come from such modes of looking at our respective arts, and found what I have to say upon a logical, and therefore correct, appreciation of what a scientific art really is.

Any art consists in a body of maxims of practice or rules, together with the knowledge, more or less accurate, upon which the rules are founded. The rules are what is commonly called the art; they are the immediate grounds of the practice or doing. The knowledge constitutes the reasons for the rules, for what is done. There is no art so rude but that some reasons may be given for its rules of practice; the position of an art in the scale of arts depends on the validity of its reasons, that is on the quality of the knowledge upon which its practice is based. If we can give no better reasons for our practice than that experience justifies it, though such reasons are valid enough in their way, the art is in the condition of an empirical art; it is not scientific at all. I must, however, make a reservation here to avoid misconception. Do not think that I am crying down experience. Experience is either the confession of ignorance or the test of truth. Used in the former sense it characterizes the empirical art; in the latter sense it is one of the weapons of scientific research. On the other hand, if the rules of an art are founded on knowledge of a higher quality, if we can justify our practice by an appeal to knowledge in that form which is called science, *i.e.*, to knowledge we know to be true—then the art is a scientific art.

Now the rules of an art belong to that art and not necessarily to any other, and the knowledge that is mere empiricism is the property of the art to which it refers. But the knowledge of the higher quality, the knowledge which has been tested and found to be true, which has been generalized and organized into methodical arrangement—this highest kind of knowledge that we call science—is the common property of all arts that can claim to be beyond the stage of empiricism; the claim to this kind of knowledge establishes a community, a relationship between arts which is the highest and most enduring relationship that can exist.

This is the relationship between medicine and pharmacy that I propose to deal with to-night; this relation that comes of a common appeal for the reasons or grounds of practice to knowledge in its highest form.

Both arts now assuredly, however deeply in days gone by they may have struggled in the darkness of the slough of empiricism, are emerging fast into the daylight of science. The rules by which the practitioner of each is now guided can own a better and a surer warrant than blind experience can give; their methods are the methods of scientific observation and reasoning; their aims are true knowledge concerning nature.

So then, I have supposed that if I—as one much interested and occupied in what belongs to the scientific aspects of the medical art—were to come down and from my stand-point give you—who are much interested and occupied in what belongs to the scientific aspects of the pharmaceutical art—some thoughts of mine about these our scientific relations, I might perhaps not unprofitably occupy your minds as I have certainly profitably occupied and gratified my own.

And, to complete the argument, I have thought of medicine and pharmacy as scientific arts, whose material is very different and whose rules of practice and final purposes are distinct, but which in their respective fields seek to work out their purposes by similar methods of research and by the application of the principles and results of the same two departments of science—physics and chemistry to wit. It is this use of similar methods and this common application of physics and chemistry that constitutes the particular scientific relationship about which I desire to speak. The use of these methods and the influence of these two sciences have given special features and a special direction to medicine. In my view thereby is imposed on pharmacy an obligation to develop or acquire corresponding special features and to pursue a corresponding direction.

Before I proceed to detail what these special features are in the one case and should be in the other, let me justify the position that there should be any correspondence at all, let me explain the obligation. And for greater clearness I will throw the idea into the concise form of a proposition—"That the condition of medicine and the direction in which it is tending at any given time ought to be reflected in the condition of pharmacy, and the direction in which it is tending at the same time."

This proposition shall be imperfectly and briefly proved by some abstract considerations—by showing the necessity on philosophical grounds of the reciprocal relations.

I have said that practice implies an end or purpose, and that purpose is the satisfying a need. This has been the starting-point of my thoughts, and when reduced to the concrete expression of what are the actual purposes of medicine and pharmacy, this abstract statement will give an exact definition of the nature and scope of those respective arts. The statement requires no proof—no one would deny it. It is expressed in the fact that arts usually precede science,—that is the knowledge on which they are founded. The need that things should be done causes attempts, rude at first, to do the things, then by the exercise of the art the ways of doing are improved, and science later on still further improves the practice and furnishes reasons and grounds for the rules. If we start from the other end, and look at the matter from another point of view, the statement holds good. Science in the abstract is founded on a need, the need for knowledge,—on the condition that the knowledge be true,—and its end is to collect, to verify, and to communicate knowledge. Then science naturally falls into departments, for the facts of nature are not all of the same kind, and this division of natural phenomena must be preserved and indicated in the divisions of science. And, when all the available knowledge about all departments of Nature has been collected and arranged, it will be found that what we have got is really assertions about matters of fact. We have got knowledge, but it is not on that account of any use to us—we have got what is called "pure science." In medicine and pharmacy both we have a good deal of pure science, and it is rather in the way than otherwise, as some people think. At least, it introduces difficulties, one of which I see your own Pharmaceutical Society has groaned over, and which may be sufficiently described by the question—"How is a man to live whilst he prosecutes pure science?" It is quite certain that in these times pure science will not feed and clothe its votaries, and yet these votaries themselves and their fellows need to be fed and clothed. These sort of needs, connected with the conditions under which mankind exists, necessitate that our knowledge, whether in the form of pure science or not, should be made use of—applied. Thus we get applied science, or what may, perhaps, with more propriety be termed practical science. And just as in science there are departments corresponding to the different kinds of natural phenomena, so there are numerous departments of practice corresponding to the varied wants and needs of human beings. Thus, whether we build up from the origin of art or pass downwards from the state of an art when it has become scientific, we find that an art is defined, marked out by its purpose or end.

The purpose or end of pharmacy originates in the needs and demands of medicine. Man needs that his health be secured, that disease should be prevented, alleviated, and cured; and to this end the art of medicine exists. To fulfil its end, medicine requires also means and agents—preventive and remedial agencies, let us say. We may be sure that so soon as the desire or necessity for dealing with bodily ills arose, the necessity for means to deal with them would also arise. To provide these agencies is, I take it, the final purpose and end of pharmacy. It is the proper business and function of the pharmacist to provide the physician with those agencies wherewith the physician may proceed to fulfil the purpose and end of his art. This way of looking at their respective final purposes at once links medicine and pharmacy in the closest bonds of union and separates them as distinct departments of practice. And so, I think, it ought to be. This way of looking at the matter, too, regards the pharmacist in a very different aspect to that of the mere dispenser of physicians' prescriptions or the compounder of drugs according to legalized formulæ. The dispenser, important though his functions be, is not necessarily a pharmacist in the sense in which I would use the term, as one who practises a scientific art. In putting the matter in this way, I do not mean that the physician simply asks for drugs which he enumerates and for whose preparation he gives directions in a standard Pharmacopœia, which drugs and which preparation the pharmacist supplies and performs. Viewed from the side of art alone, the practice of the physician is to apply known remedies, when he has brought his case under certain rules. From the scientific side, the physician constructs the rules according to which he is to act from the data of the case and the knowledge he possesses. In both cases, the problem presented is one of causation, an inquiry into cause and effect. But in the first case, what may be termed the practical view of causation is taken, that is certain prominent, serious, or critical circumstances are selected as being practically and for the purpose efficient causes. In the other case, cause is to the physician an aggregate of numerous, complicated and interacting conditions or circumstances all concerned positively or negatively in the causes and effects. Take, for instance, the action of drugs—to say nothing of the conditions connected with disease itself; a drug, more especially a vegetable substance, may have many possible ways of acting consequent on the complicacy of its composition or properties. The question then is what is the precise property of the drug that affects the system or what the circumstances of the system that co-operate in producing the effects. Here a large field is opened up to the pharmacist. The physician may appropriately need that the pharmacist should by his work at least eliminate and disentangle such circumstances as depend on the composition and properties of the agencies with which he has to do. The physician, meanwhile, will have his hands full enough if he concerns himself with inquiry into the conditions which belong to the body and its derangements—the things with which he has to do. Time would fail me to pursue the analysis further, and, in this way, to state other specific and detailed purposes which mark off medicine and pharmacy as distinct departments of scientific practice. I have said enough, I will hope, to set you thinking, if you are so minded, for a long while. I have been particular upon this point, because I think that though these relations, through need and purpose, that I have sketched out, are recognized in a general way and are certainly acted upon, yet, being admitted, fallacious ideas as to the grounds of the relations and as to what they involve and lead to are not uncommonly entertained.

I am conscious that much of this that I have said is neither new to you nor other than very dry discourse. Let me then now invite your attention to what may perhaps prove more interesting. Let us inquire into the parallel history of medicine and pharmacy with a view to see if any light can be thrown on this matter of reciprocal relations by the relations and circumstances that have existed in the past. We may find that it would have been better had such relations been acted up to; we may find that progress has been hindered because such relations have not been acted up to; or perhaps we may find that the principle involved has been gradually evolved out of the past.

The starting-point in such an inquiry would naturally be where first we meet with a well-defined distinction between the art of preparing remedies and the art of using them. But it will be, if I mistake not, interesting and helpful to go back further than the comparatively late period at which such a distinction first appears. I shall therefore, make no apology for going back to the beginning of the stream of medicine and conducting you rapidly through its whole course.

The beginning of the main stream of pure medicine, true to nature, is in the conjunction of little rills. In the midst of gross superstition and idolatrous rites the first records of reason and experience appeared. Very ancient medicine is a very dark page and very ancient pharmacy was, so far as I can see, quite as dark.

The deity Isis by her anger caused all diseases, and Isis by her favours cured such as she pleased. Such was the medicine and pharmacy of the ancient Egyptians, and they were the first nation, so far as we know, that cultivated medicine. Even down to the time of Galen several compound remedies in the materia medica bore the name of the Egyptian deity Isis. Among the Greeks, every evening was burned in the temples dedicated to Isis a composition that contained sixteen drugs, and the sick were made to sleep in the temples in order that the oracles might reveal to them the remedies they should use to their cure.

The origin of medicine was much the same in all countries.* Greece has the credit of having first evolved system, or what may pass for system, out of the chaos of superstition. Pythagoras, who lived B.C. 580, practised and enjoined a life of sobriety as one of the means of preventing disease. He used plants in medicine and knew the virtues of squill, aniseed, mustard and the cabbage; but then these virtues were, to Pythagoras, magical, and

* Corresponding to the priest-physicians of Egypt Greece had her caste, the sons of Æculapius.

were evoked by divination and magical rites. One of the followers of Pythagoras, Alcmæon, may be said to have been the first anatomist. But as to anatomy, this study as an aid in medicine was really only commenced at a very late period, in consequence of the stringent laws of every religious creed. The knowledge of human anatomy was entirely speculative up to A.D. 1315, when Mondini de Luzzi first dissected the human subject before his pupils.

What was good and useful in the knowledge of his predecessors was gathered up by Hippocrates (the "Father of Medicine"), B.C. 460, who, on a basis of experience and philosophizing, founded scientific medicine. Hippocrates divided medicine into three branches, dietetics, pharmaceutics and chirurgics. The practice of these times was, however, extremely rude. The practice of pharmacy was of this kind: euphorbium was one of the few known purgatives, but it was acrid; to diminish the acridity the then pharmacopœial directions ran thus, "pour the juice drop by drop on dried figs." Thus a remedy for dropsy was manufactured.

The immediate followers of Hippocrates constitute the "dogmatic" school, and we may dismiss them with the reflection that they illustrate the truth of a wise modern saying that "men often dogmatize most who are least supported by reason."

The first beginnings of that store of knowledge of things from which afterwards the materia medica was selected is associated with the conquests of Alexander the Great, and of Philip of Macedonia.

Aristotle (B.C. 384) had, thanks to Alexander, unrivalled opportunities for the prosecution of scientific research in natural history, and he used them well. To him, and to his successor, Theophrastus, who did for botany what Aristotle did for zoology, medicine and pharmacy are indebted in no ordinary degree. During the time of the Ptolomies, who succeeded Alexander, science flourished and progressed greatly. It will not be out of place just to point to Ptolomy the First, the King of Egypt, as an example even to us very advanced moderns of what may be done for knowledge by an enlightened ruler. Ptolomy founded at Alexandria a society called "Museum," the members of which were maintained at the public expense in order solely to carry out philosophical research, and to advance science and the arts; subsequently this institution became the most celebrated school of medicine in the world. This was 300 years before the Christian era. The vast extension of commerce at this time caused a great development in the knowledge of drugs, and attracted the attention of physicians to this department especially.

Then arose the empirics, a school that gave rules for observing and rejected theory. This school regarded chiefly symptoms, and sought by observation a knowledge of how diseases could be most readily cured. What the empirics themselves made of their doctrines, although they gave a type to the healing art in subsequent ages, may be gathered from the mode of treating epilepsy as practised by a celebrated empiric, Serapion. This mode consisted in the administration of camels' brains, the excrement of the crocodile, turtle's blood, and such like things. I cannot avoid a piece of satire here, for which you must forgive me. Young ladies afflicted with anæmia and phthisis 2100 years after Serapion's time, only a year or two ago, were wont to resort to the slaughter-houses of Paris to drink the warm blood of fresh killed bullocks! The pharmacists, true to their vocation, have provided an extract of bullock's blood made up in the form of pills.

Two centuries before the Christian era much attention came to be bestowed on toxicology. Attalus Philopater, who died B.C. 133, left the cares of his kingdom, Pergamus, to cultivate in his garden poisonous plants (aconite, hyoscyamus, and hemlock), and to devise antidotes against them. The name of his successor, Mithridates, is familiar enough in pharmacy; his antidote of fifty-three ingredients beats poly-pharmacy out of the field. Asclepiades, who lived B.C. 90, must not pass without notice. He, aided by his successor, Themison, founded the "Methodic school, which aimed at a correct practice by reducing pathology to a few principles from which indications for treatment could be easily seen.

Arrived at the Christian era, Celsus's name comes naturally as the first of note. But beyond the fact that Celsus was an industrious collector of what others had said and done, and wrote elegant Latin, his influence on medicine would appear to have been small.

About this time (A.D. 100) we get the first important treatise on materia medica in a learned and complete account, in five volumes, by Dioscorides, of the then state of natural history and remedial agencies. In this work nearly 1000 articles were described, and it remained a text-book down to modern times.

The methodic school did not survive long, and was split up into others, of which the chief was the "Eclectic" school. The eclectics tried, what others have often tried to do since, to reconcile discordant opinions as to medicine and its practice, and they selected from each system that which they deemed best.

Archæus was a celebrated eclectic, and an enlightened practitioner, who used many remedies with discrimination, and pursued medicine in the true Hippocratic spirit. To show how often knowledge gained from the ancients, supposed to have been due to remarkable genius or industry, is only the brilliant guesses of a philosophical imagination, I may cite this supposition of Archæus. He supposed that the nerves did not pass or grow from their origin to their termination in straight lines, but crossed each other like the letter X, and passed so to opposite sides, and he actually thus explained the fact that when the head has been injured on one side, the other side of the body suffers. Now Archæus never dissected in his life; his supposition was a brilliant deductive hypothesis.

(*To be continued.*)

ANILINE BLACK MARKING INK.

The following directions for preparing Dr. Jacobson's aniline ink for marking linen are quoted from *Dingler's Journal* in the *Moniteur Scientifique* for April:—

The ink is prepared by means of two solutions, one of copper, the other of aniline, composed as follows:—

(1). *Copper Solution.*—8·52 grams of crystallized chloride of copper, 10·65 grams of chlorate of soda, and 5·35 grams of chloride of ammonium are dissolved in 60 grams of water.

(2). *Aniline Solution.*—20 grams of hydrochlorate of aniline are dissolved in 30 grams of distilled water, and to this are added 20 grams of solution of gum arabic (1 part of gum to 2 of water) and 10 grams of glycerine.

By mixing in the cold 4 parts of the aniline solution with 1 part of the copper solution, a greenish liquid is obtained, which can be employed directly for the marking; but as this liquid can only be preserved a few days without decomposition it is advisable to keep the solutions separately until the ink is required for use. The ink may be used either with a pen or a stencil plate and brush; if it do not flow freely from the pen it may be diluted with a little water without fear of weakening the intensity of the colour. At first the writing appears of a pale green colour, but after exposure to the air it becomes black; or it may be changed to a black colour immediately by passing a hot iron over the back of the fabric, or heating it over the flame of a spirit lamp. As, however, a dry heat is apt to make the fibre saturated with the ink brittle, it is preferable to hold the marked fabric over a vessel containing water in full ebullition; the heat of the vapour is sufficient to determine almost immediately the reaction by which aniline black is formed.

After the steaming the writing should be washed in hot soapsuds, which gives the ink a fine blue shade. The ink is not acted on by acids or alkalies, and if care be taken that the fibres are well saturated with it there is no danger of it being removed by washing.

The Pharmaceutical Journal.

SATURDAY, MAY 15, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed " Pharm. Journ."*

THE ILLEGAL SALE OF POISON.

THE papers of last Monday contained reports of an application made to Mr. COOKE, the magistrate at the Clerkenwell Police Court, which serves to show that many persons are not aware of the liabilities they incur by selling any of the articles included in Schedule A of the Pharmacy Act.

As stated in last week's Journal, an oil and colourman in Islington was fined for selling oxalic acid without a label bearing the name of the substance, and the word " Poison," as prescribed in clause 17 of the Act. We took occasion to point out that this was not the only infringement of the Act which had been committed in this case, inasmuch as clause 15 provides that any person who sells a poison under any circumstances without being registered as a Pharmaceutical Chemist or Chemist and Druggist as the Act provides, commits an offence which renders him liable to prosecution, and to the payment of a penalty of five pounds for every such offence. This penalty may be sued for and recovered in England and Wales by plaint under the provisions of any Act in force for the more easy recovery of small debts and demands, and in Scotland by action before the Court of Sessions, the Sheriffs of Counties, or the Magistrates of Burghs.

In fact, any person who sells poison, without possessing the legal qualification of the chemist and druggist, thereby renders himself liable to a special penalty over and above the penalty to which he, in common with the chemist and druggist, would be liable for selling poison without conforming with the regulations of the Pharmacy Act.

It appears from the statement of Mr. ALDRIDGE that since he was fined last week he has received a letter from the Solicitor of the Pharmaceutical Society informing him that he has incurred a penalty of five pounds, under section 15 of the Pharmacy Act, and that in default of payment proceedings will be taken against him. The magistrate of course told him that so far as his court was concerned he had nothing further to do with this matter, and that the applicant should consult his solicitor. No doubt if he adopts this course he will learn what is actually the position in which he has placed himself, and will find reason to regard the sale of poisons as a business not likely to be profitable to him. It may, therefore, fairly be expected that, so far as he is concerned, there will be no further need to complain of interference with the proper functions of chemists and druggists in this respect.

We have thus prominently referred to this case because the numerous complaints that have reached us as to the illegal sale of poisons serve to show that the practice is very general, and that it amounts sometimes to a serious interference with the business of the chemist and druggist. In the course of the discussion that took place last week, several members of the Council expressed the opinion that the authorities of the Society had hitherto been too lenient in regard to this matter, and it was now high time energetic measures should be taken with the object of enforcing the provisions of the law.

We fully concur in this view and consider that if in addition to the propriety of observing the law any further argument were needed to show that action is desirable at the present time, it may, we think, be gathered from the derisive and defiant tone of some letters which have appeared in the *Standard* upon the subject. Thus, for instance, a correspondent of that paper, signing himself " Cornish Miner," referring to the letter of the Secretary and Registrar of the Pharmaceutical Society, explaining how it was that Mr. ALDRIDGE had made himself liable to a twofold penalty, expresses himself confident that it " will not fail to raise a smile in many quarters." In justification of this belief he goes on to say that although he is not on the Register of Chemists and Druggists he has often sold arsenic but has never been fined, and that he has just sold 700*l.* worth of it unhindered and without undergoing prosecution. The " Cornish Miner " evidently classes the Pharmacy Act and the Register of Chemists and Druggists with the kobolds and bogies which miners are familiar with as being very often talked about but very seldom seen, and his letter merely demonstrates his individual want of information as to the law affecting the sale of poisons.

Another correspondent signing himself, " A Colourman," writes in a somewhat indignant strain, and asks how he is to carry on his business in supplying people with paints and plaster of Paris if he is to be prosecuted for selling poison? His opinion of the labelling of poisons is that you may as well seek to compel tradesmen who deal in razors and revolvers to label them dangerous, and he evidently entertains a profound disbelief in any powers of the Pharmaceutical Society to enforce regulations as to the sale of poisons, or to protect the members of the drug trade from illegal competition, or interference with their proper business.

Obviously there is need of enlightenment among colourmen as well as Cornish miners, and as the Pharmaceutical Society is charged with the enforcing of a law intended for the public protection, it is no less on that ground than out of regard for the interests of those it has more immediately to consider that it is incumbent upon the Society to make its power felt and respected.

M. DUMAS' REMEDY AGAINST PHYLLOXERA.

About six months ago it was mentioned in this Journal (before, p. 404) that M. Dumas had recommended a solution of an alkaline sulphocarbonate as an effective insecticide, especially suited to cope with the phylloxera which have ravaged so seriously several of the wine districts of France. The sulphocarbonates are compounds of sulphide of carbon with metallic sulphides, which are slowly decomposed with evolution of sulphurretted hydrogen. The importance of such an announcement, if it should prove well founded, may be estimated by the fact that apparently from a dread of introducing this pest the Government of Italy has forbidden the importation of plants of every description into that country after the 18th inst.

The vinegrowers of France will, therefore, have heard with pleasure, from M. Dumas' recent report to the Academy, that actual experiment has shown that the alkaline sulphocarbonates act very energetically against the phylloxera without injuring the vitality of the vines, in fact, in some cases the vines have apparently been invigorated by the application. The phylloxera are reported to disappear wherever the solution of a sulphocarbonate penetrates; the penetration into the soil being favoured by rains, as the salt is soluble in water. At first the sulphocarbonate of potassium was used, but experiment has shown that an equal weight of sulphocarbonate of sodium is even more efficacious, whilst it is less expensive.

The sulphocarbonates not being commercial salts it has been necessary to initiate a new manufacture; the price is probably, therefore, higher now than it will eventually become. But at present the cost of sufficient to dress a hectare of land is estimated at from 100 to 150 francs.

THE APPOINTMENT OF A PUBLIC PROSECUTOR.

We are glad to notice that on Monday night the Home Secretary stated, in reply to a question put in the House of Commons, that it is the intention of the Government to introduce a bill during the present session to provide for the appointment of a public prosecutor in England.

THE BANK HOLIDAY.

Few acts of the Legislature have received so widespread and immediate adhesion, not only to their letter, but to their spirit, as has attended the Bank Holidays Act. We venture to express a hope that Monday next may show no falling off in this respect, especially amongst chemists and druggists. It is with satisfaction we learn that the Society's School of Pharmacy will not be open on that day.

Mr. Francis Sutton, of Norwich, has been requested to supply the apparatus and chemicals required by the Arctic Expedition for their experiments on the specimens of sea water which they will collect in the course of their voyage.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

May 12th, 1875.

Present: Messrs. Allchin, Benger, Bottle, Carteighe, Corder, Haselden, Linford, Martindale, Moss, Schweitzer, Taylor, and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MAJOR EXAMINATION.

One candidate was examined, and declared qualified to be registered as a Pharmaceutical Chemist, namely:—

Herbert, John .... Kingston-on-Thames.

MINOR EXAMINATION.

Eight candidates were examined. *Six* failed. The following *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

Jackson, Henry John ....Bawtry.
Varney, Henry George ....Oxford.

These names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The undermentioned Certificate was received in lieu of the Society's Examination:—

Certificate of the College of Preceptors.

Jones, Ivor Lloyd.................Swansea.

NORTH BRITISH BRANCH, EDINBURGH.

Annual Meeting.

The annual meeting of the North British Branch was held in the Society's rooms on Monday forenoon, 10th May, at 12 o'clock, Mr. W. Gilmour in the chair.

The Chairman called on the Secretary to read the following annual report:—

The Annual Report.

The Council have much pleasure in submitting for approval the usual annual report of the proceedings of the North British Branch of the Society during the year 1874.

Removal from the rooms formerly occupied was effected in the month of May last. The reasons for the change from St. Giles Street were so fully given at the time, that no further reference need be made, beyond reminding the meeting that additional space was urgently required to carry on the business of the Society in all its departments. Increased accommodation having been obtained in the present rooms, and at a less annual rent, the Council have much pleasure in intimating, that the existing arrangements are most comfortable, and suitable in all respects for the purposes of the Society.

In the large front room the museum is now seen to some advantage, while the cabinet for the use of students, containing as it does specimens of nearly all drugs and preparations in the Pharmacopœia, is found well adapted to assist those who are preparing for their examinations. This room is also available for conducting the Preliminary examinations, while, for the Minor and Major, space is afforded for distinct tables, at which are conducted the oral examinations on prescription reading, botany, materia medica, pharmacy and chemistry.

The centre room forms an admirable library and general reading room, while during the examinations a large dispensing counter, with all convenient appliances, is here used for practically testing efficiency in this department.

The back room, which is of a convenient size, has been fitted up as a laboratory, with benches and all other conveniences, and here the Minor and Major candidates perform their practical chemical work in connection with their respective examinations.

The numbers who have presented themselves before the Edinburgh Board during 1874, are as follows:—Preliminary, 134; Modified, 22; Minor, 180; and Major, 6—in all, 342. The results of these examinations having from time to time been published in the *Pharmaceutical Journal*, no farther reference need be made excepting an expression of regret that so many have failed to pass. With this feeling in regard to the number of failures, the Council express a hope that there may be for the future a complete change, and that young men knowing the requirements will better prepare themselves for the different subjects on which they are to be examined. It may also be noticed that the number of applicants in September was exceptionally large, arising doubtless from a desire to escape the practical chemical work, which came into operation in the beginning of October.

In connection with the examinations in Scotland the Council have again to notice the kindness of the London President, Mr. Hills, for having so handsomely provided a fund from which to give a prize of books to the candidates passing highest in the first division at the Minor examinations in Edinburgh.

The following is a statement of the operation of this fund during the year 1874:—

Cr.

		£	s.	d.
March 18.	Cash paid for Books to B. L. Mackay, Inverness	1	0	6
May 12.	Cash paid for Books to G. A. Shum, Edinburgh	1	0	3
July 30.	Cash paid for Books to R. K. Currie, Glasgow ..	1	1	0
Sept. 22.	Cash paid for Books to C. J. Cowper, Edinburgh	0	19	0
Dec. 31.	Balance over and carried to next year's account	0	18	7
		£4	19	4

Dr.

		£	s.	d.
Jan. 1.	Cash in Bank	2	10	0
June 5.	Cash from London	2	9	4
		£4	19	4

The Council are glad to find from the Secretary that he has issued in connection with the Branch during the past year thirty-five tickets for lectures on chemistry, materia medica, and botany.

The scientific meetings for the session just closed have been six in number. The subjects introduced were deeply interesting, and the meetings well attended. To those gentlemen who have contributed papers the Council beg to tender their warmest thanks.

Thanks are also offered to those who have made presentations to the library and museum. The names of Mr. D. R. Brown, Mr. Baildon, and Mr. Tait are especially worthy to be remembered for having been so liberal in their donations.

The opportunity afforded of using the museum and reading-room has been fairly taken advantage of. Thus, from January 1st to December 31st, 1874, twelve hundred and forty-eight visits have been made by young men, while from the commencement of opening the rooms for this purpose in January, 1873, up to the present date, no fewer than two thousand six hundred and two visits have been made; the names entered daily in the visiting-book proving the correctness of this statement. Last February a division was made in entering those who used the rooms before four o'clock and those who came after seven in the evening. The result of this will be communicated in the next annual report.

The demand for books from the library has also improved. The books show that during last year 160 volumes have been given out, while from January 1st, 1875, to beginning of May, 50 volumes have been in use.

The Council refrain from making any remarks upon the Adulteration Act now in process of being amended. They have not been uninterested in its progress, and beg to thank the London Council for the assistance they have given and the care they have evinced, in their endeavour to render the operation of such an important Act more perfect and less objectionable than it has hitherto been.

It is with regret the Council feel compelled to notice a memorial recently sent from Glasgow to the London Council, wherein special reference is made to the Board of Examiners in Scotland, with certain inferences regarding the operation of the examinations generally upon young men entering the business of chemist and druggist. It cannot but be viewed as a matter of satisfaction, that the tenor of the memorial, so far as can be judged by public expression, is considered unfair and uncalled for by a great majority of those connected with pharmacy in the West of Scotland. The aim of the Society has always been to make the Council and Board of Examiners fairly representative bodies for Scotland, and if the Society has at any time failed to carry this out, it has arisen entirely from difficulties in the way of getting parties to act. At present there are four representatives from Glasgow in the Council, and one from the same city in the Board of Examiners, and those belonging to the former cannot but feel that the course followed by their brethren in the west has shown an apparent want of courtesy in not having taken means to indicate the nature of the memorial which they intended to send to London, more especially as it has transpired that in framing the document it was conveyed that the Edinburgh brethren were at one with the memorialists, while such was not the case. Other three gentlemen from the country in addition to four from Glasgow have seats in the Council, and it will be for the voting to-day to declare whether the members from a distance are to form a greater proportion than 7 out of 15.

It may be farther remarked that the constitution and appointment of the Scotch Board of Examiners is somewhat different to the election of to-day, inasmuch as, the Council just about to be elected will, as usual, be called upon in December to nominate eight parties to act as an examining board. This nomination must be approved by the London Council, and confirmed by the Privy Council. Any names therefore of qualified pharmaceutical chemists who are desirous of acting as examiners in Edinburgh, will be gladly received and fairly submitted, as in the past, along with the present members, for consideration before sending the list up to London.

As to the examination having produced a dearth of assistants and apprentices, or as to the question of the present fees being changed, the Council would rather, in the meantime, refrain from giving an opinion. They would simply object to any alteration of a system which only came into operation so recently, after full consideration by the two Examining Boards, the Government Assessors, and the concurrence of the Privy Council. Six months they feel is too short a time during which to test whether the alteration has been right or wrong, and the Council have no doubt that if after a fair trial injustice has been done or any error committed, matters will be so arranged as to give satisfaction to all.

The Council cannot close the report without alluding to the sudden and unexpected death of Mr. Daniel Hanbury. They feel that the removal of so able and gifted a man must be felt not only as a loss to the cause of pharmacy in this country, but throughout the continent of Europe and in other places where his name and labours were so well known and so highly appreciated. Modest and unassuming in manner as he was highly gifted intellectually, his memory cannot fail to be cherished in connection with our own Society, whose interests he had so much at heart, and in whose cause he so successfully laboured.

The approval of the report was moved by Mr. Davison, Glasgow, and seconded by Mr. Blanchard.

Mr. Currie, of Glagow, explained that no discourtesy whatever was intended to the Edinburgh Board in the memorial which had been sent to the London Council. He further explained that the feeling in Glasgow was not of a personal kind, but was simply an objection to the system pursued in regard to the election of Council and Board of Examiners. He thought that members of both boards ought to be drawn from a wider area than hitherto; in other respects he had no fault to find with the report of the Council, but hoped that ere long an Examining Board would sit and act in Glasgow if not twice, at least once a year.

Mr. Mackay explained that from the very first Glasgow and other parts of Scotland had been kept in view in forming the local Committee, while in regard to the Board of Examiners several unsuccessful endeavours had been made to get parties from Glasgow and elsewhere to act upon the board. He knew that he only expressed the feelings of the Council in Edinburgh when he stated, that they would at all times be glad to receive the names of qualified parties to take a share in the examinations, and reminded the meeting that the month of December was the proper time for sending up a list of names to London for appointment and approval by the Privy Council.

Mr. Anderson, of Musselburgh, was glad to hear an explanation from Mr. Currie that there was no want of courtesy intended by their Glasgow friends to the Board of Examiners in Edinburgh. He had long thought, however, that the fees retained by the Society in cases of failure were excessive, and ought to be reduced.

Mr. Fairlie, of Glasgow, took exception to the paragraph in the report wherein a remark was made in reference to their Edinburgh brethren not being acquainted with the nature of the memorial proposed to be sent to London. He certainly had conferred with the President and Vice-President of the North British Branch in regard to some of the leading points in the memorial, while for the preamble to the said memorial, which seemed to be the objectionable part of the document, he felt himself chiefly responsible. He begged, however, distinctly to disclaim any intention to slight the Board in Edinburgh, for the members of which he had the greatest respect, and, as already stated, he had less hesitation in making this statement as he might be considered the author of the preamble itself.

Mr. Kinninmont, of Glasgow, said that he had supported the memorial up to a certain point, but he repudiated entirely the obnoxious attack which had been made on the examiners in Edinburgh. He thought his Glasgow friends were called upon to make an apology, for as yet no proper retractation had been made. He also bore testimony to the fact that he himself had repeatedly tried, but in vain, to get some of his friends in Glasgow to allow their names to be put in nomination for the Board of Examiners in Edinburgh.

Mr. Currie said Mr. Kinninmont was a party to the whole thing, he and other two having had the memorandum to draw up, but he did not know until afterwards that Mr. Kinninmont had not seen the memorial before it was finally sent to London. He (Mr. Currie) thought they had no power to withdraw the memorial.

Mr. Kemp, of Portobello, thought the meeting was losing sight of the object they had in view. The question before them was one of courtesy. He had frequently seen individuals belonging to public bodies of which they themselves were members acting injudiciously towards their fellow members—and this seemed to be a similar case, as Mr. Fairlie and others in Glasgow belonged to the Edinburgh Council, and he thought they ought to have communicated the intentions of the Glasgow meeting more thoroughly than they did. So far from the fees being reduced in cases of failure, he thought they should be increased, as young men were constantly coming up unprepared, and thus costing the Society a good deal of money.

After some remarks from Mr. Anderson and Mr. Davison, Mr. Tait, as Chairman of the Board of Examiners for Scotland, thought Mr. Currie and Mr. Fairlie ought to withdraw that part of the memorial where discourtesy was plainly inferred. From his long connection with the Board he begged to state, that there was considerable difficulty to get suitable men to act as examiners. Besides, the whole subject of examination was discussed before the deputation went to London, and he considered it too premature to make the attempt to change the system which it had been decided fairly to try by a majority of all concerned.

Mr. Gilmour was glad that the subject had been so fully discussed. He expressed his regret that the movement in the west had not been conducted somewhat differently, because there was but one feeling in Edinburgh and he could not express this too strongly, and that was to take their Glasgow friends along with them in any matter connected with the encouragement of true pharmacy and the operations of the North British Branch of the Society.

Mr. Young took exception to Mr. Fairlie founding so strongly upon sending notices regarding business meetings of the local Association, in Glasgow, and reminded him that the Council meetings of the North British Branch were entirely of a different character to those of any other Association in Scotland.

The Chairman then put the report to the meeting which was carried unanimously;—Messrs. Currie and Fairlie requesting the following notice to be inserted as part of the meeting:—

"The Ex-President and Secretary of the Glasgow Association were present, and previous to the adoption of the report of the Council disclaimed that there was any discourtesy intended on the part of the Glasgow memorialists, either in the preamble or substance of the memorial, with regard to the Scotch Board of Examiners."

The Secretary then intimated the result of the scrutiny by the Committee appointed to count the votes, and declared the following gentlemen to be duly elected as Council for 1875-6; the names are arranged alphabetically, and not according to number of votes:—William Ainslie, Edinburgh; H. C. Baildon, Edinburgh; James Buchanan, Edinburgh; George Blanshard, Edinburgh; Wm. Duncanson, Stirling; Thos. Davison, Glasgow; Daniel Frazer, Glasgow; Wm. Greig, Glasgow; Alex. Goan, St. Andrews; Wm. Gilmour, Edinburgh; David Kemp, Portobello; Alex. Kinninmont, Glasgow; A. Seath, Dunfermline; Wm. Tait, Edinburgh; James R. Young, Edinburgh.

Mr. Davison proposed, and Mr. Young seconded, that Mr. Gilmour be appointed President for another year.

Mr. Tait proposed, and Mr. Ainslie seconded, that Mr. Kinninmont, Glasgow, should continue as Vice-President; both these appointments were carried unanimously, and with acclamation.

Committee for library, museum, and general purposes:—Messrs. Young, Ainslie, Gilmour, Baildon, Buchanan, Kinninmont, and Tait.

Mr. Blanshard proposed, and Mr. Davison seconded, that Mr. John Mackay should be asked to continue his services as Honorary Secretary.

After a few remarks from Mr. Gilmour, Mr. Kinninmont, and Mr. Mackay, the meeting adjourned.

The Dinner.

The Council and other friends dined together in the evening at the Balmoral Hotel. Mr. Gilmour in the chair, and Mr. Kinninmont croupier.

The following toasts were proposed and responded to:—"The Queen" and usual loyal toasts were given by the Chairman, who also proposed the toast of the evening, "The Pharmaceutical Society;" "The Council in London" by the Croupier, responded to by Mr. Mackay; "The Honorary Members in Scotland," responded to by Professor Archer; "The Lecturers to the Society in Edinburgh" by Mr. Tait, responded to by Dr. S. Macadam and Dr. Craig; "The Memory of Jacob Bell" by Mr. Kemp, of Portobello; "Friends from Glasgow" by Bailie Blanshard, responded to by Mr. Rait; "The Chairman" by Mr. Ainslie; "The Secretary" by Mr. Noble.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eleventh general meeting of this Asssociation was held at the Royal Institution, April 22nd, Mr. A. H. Mason, F.C.S., President in the chair.

Donations to the library of *The Pharmaceutical Journal*, and the *Canadian Pharmaceutical Journal*, and to the museum of a specimen of Carnauba Root from Dr. Symes, were received and thanks voted to the donors.

The President then said: Gentlemen,—It is with extreme pleasure that I comply with the request of Mr. Thomas Morson, and in his name present to the Association this beautifully executed portrait of his father, the late Mr. Thos. Newborn Robert Morson. It was the previlege of some present to have enjoyed his personal friendship, but he has left behind a name so well-known to chemists throughout the world, that I need not say more than express a hope that this picture will for many years adorn the walls of our museum, and that he will be looked upon as an example for us to follow, and our students to emulate. I beg to move, "That the best thanks of the Association be given to Thos. Morson, Esq., F.C.S., of London, for his acceptable donation to the museum of an admirably faithful portrait of his father, the late Thos. Newborn Robert Morson, Esq., F.C.S. who was so highly esteemed by the members."

Mr. Abraham seconded the motion. He had had the pleasure of a personal acquaintance with Mr. Morson during many years. He believed that Mr. Morson was the first and most distinguished of those who devoted themselves to the preparation of the vegetable alkaloids, and other active constituents of vegetables, when these came into demand fifty years ago and subsequently. He was a talented and useful man, kind, hospitable, and genial, and was much loved in a large circle. The portrait was an excellent likeness.

The motion was carried unanimously by acclamation.

Dr. Symes made some general remarks on carnauba root, which he described as a new remedy from Brazil, acting as an alterative, and used as a substitute for sarsaparilla. He also exhibited a sample of extract made by adding 1 lb. to a gallon of water, and heating to boiling point. It is then allowed to stand, strained, and evaporated to 12 ounces, 4 ounces of rectified spirit are then added He also exhibited a fine sample of salicylic acid, and spoke of its use as an antiseptic, especially calling attention to the fact that it is not poisonous.

Mr. Abraham said that carbolic acid ought to be conspicuously labelled "poison." He had spoken to the late Dr. Calvert on this point.

Mr. Parnell, F.C.S., then read a long and interesting paper on "The History of Bleaching Powder," of which the following is an abstract:—

The ancient method of bleaching cotton and other fabrics by exposure to the influence of air and sunshine was exclusively used in Great Britain up to about eighty or ninety years ago, and is still employed to a great extent in many civilized countries. This method of bleaching, which was very practicable a hundred years ago when the turn out of cotton goods in England was something like one-five-hundredth of what it is at the present time, became gradually, as the trade increased, a very serious drag upon this important industry. It is easy to understand, therefore, that the attention of manufacturers and inventors was called to the importance of introducing some improvement in the operations of bleaching. We are indebted to the French chemist Berthollet for the idea of applying chlorine for this purpose. This gentleman, who was practically engaged in dyeing and bleaching operations, observed that an aqueous solution of chlorine readily bleached vegetable colouring matters; he applied it most successfully on the large sale for his bleaching operations, and very soon chlorine water came into general use among bleachers. The compound of lime and chlorine known as chloride of lime or bleaching powder was discovered by Mr. Charles Tennant, of Glasgow, in the year 1798. This body on being dissolved in water gave a solution possessing similar properties to those of chlorine water, but at the same time could be easily stored and transported. Its advantages were quickly recognized, and the demand for it rapidly increased, bleachers preferring to pay an extra price for their chlorine to the disagreeable alternative of manufacturing it on their own premises. The manufacture of bleaching powder has steadily increased up to the present time, the present annual turn out in Great Britain being something like 100,000 tons.

The process of its manufacture as carried out by Mr. Tennant received very little modification up to within the last six or seven years. It consisted of two distinct operations, first, the production of the chlorine, and secondly, its absorption by slacked lime. The chlorine is produced by the action of hydrochloric acid, obtained as a bye-product in the alkali process, upon native binoxide of manganese. This operation is performed in stills, made of large stone flags, fitted with suitable openings for admitting the manganese, steam, and acid, and allowing the escape of the chlorine. The latter gas is conducted by pipes to the absorbing chambers, which are usually made of sheet lead in a manner similar to those used for the condensation of sulphuric acid. Lime of first-class quality carefully slacked and sifted is placed on the floor to a depth of about six inches, and on the doors being closed and luted the gas is admitted through the roof. The latter is very quickly absorbed by the lime, and the resulting bleaching powder usually contains about 36 per cent. of chlorine.

The various methods that have been proposed for the recovery of the manganese employed in the generation of the chlorine were then described, special attention being directed to the process invented by Mr. Walter Weldon, which is now becoming universally adopted. Mr. Parnell concluded with a sketch of the chemical nature of bleaching powder, and of the various analytical methods employed for its valuation.

The paper was illustrated throughout with experiments.

Mr. Davies proposed a vote of thanks to Mr. Parnell, and suggested that as it was late, the discussion should be adjourned to the next meeting.

Mr. Murphy seconded the motion, which was carried by acclamation. The discussion was adjourned.

The twelfth general meeting was held at the Royal Institution, May 6, 1875. The President, Mr. A. H. Mason, F.C.S. in the chair. Several donations to the library were received and duly acknowledged.

The President exhibited a sample of artificial vanillin, made from coniferin, and possessing the powerful odour of the natural product.

The President then called upon Mr. E. Davies, F.C.S., to open the discussion on Mr. E. Parnell's paper on "The History of Bleaching Powder."

Mr. Davies said that his remarks would be of an unconnected character as he did not intend to review the whole subject. His opinion was that bleaching powder is a loose combination of chloride and hypochlorite of calcium, based on the production of hypochlorous acid when a dilute solution was distilled with sulphuric acid added to semi-saturation, and from the analogy of the reaction when chlorate of calcium was formed. With regard to the quality of manganese as dissolving readily or with difficulty he had devised a method for getting some idea by making a coarse powder of definite size, and heating in a water-bath with hydrochloric acid of 24° Tw. The comparative time required to dissolve the manganese gives a fair idea generally, though in a case where the manganese was intersected with thin veins of quartz it had failed.

Mr. M. Murphy, F.C.S., said that he had been acquainted with the manufacture of bleaching powder for twenty-six years, and gave a description of the method employed at first. Whilst the arrangements for making the chlorine had been wonderfully improved, the absorption of it had been neglected. The necessity for men to have to enter the chambers and turn over the half-saturated lime, and to pack it when finished, was barbarous and inhuman. The inhalation of chlorine and the dust of the powder was exceedingly injurious—produced phthisis—and the work could only be carried on by the use of large quantities of whisky. It was time that some mechanical means should be discovered. He mentioned Dr. Muspratt's work on bleaching powder, and concluded by objecting to the method of testing bleaching powder, in which the proto-sulphate of iron was used, as giving results 1½ to 2 per cent. too high.

Mr. Armstrong spoke of the value of Mr. Parnell's paper, and thought that the Association might be useful in giving hints to practical men. He thought by an arrangement similar to a proof stick in sugar manufacture, exposure to chlorine in taking samples at least might be avoided.

Mr. Parnell replied at length. He did not consider that the composition of bleaching powder had been absolutely settled. With regard to chlorine in the chamber, when the packing had to be done in well-regulated works the excess of chlorine was siphoned off before opening the chamber. He thought that any arrangements for mechanical agitation of the lime and packing would necessitate too expensive a plant.

A cordial vote of thanks to Mr. Parnell concluded the meeting.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Assistants' Section.

The eighth and final meeting of the session was held in the West Hall, Anderson's University, on Wednesday, the 28th April, at 9 P.M., Mr. John C. Hunter, A.P.S., President, in the chair. There was a large attendance of members. The minutes of the preceding meeting having been read and confirmed, Mr. William MacKenzie, A.P.S., delivered a most interesting lecture "On the Detection of the Fourth Groups of Metallic Oxides."

At the conclusion of the lecture several members made a few remarks, and the Chairman proposed a hearty vote of thanks to Mr. MacKenzie for his very interesting and instructive lecture, which was carried by acclamation.

The Secretary (Mr. John Foster) then read the annual report. In the report the Committee congratulated the Association that the number of members on the roll for this session is 96, against 25 last session. This great increase of members was attributed to various causes; foremost among which was mentioned the library, which, although not very extensive, is exceedingly select. There being a sum of £20 still in hand for the purpose, the library will receive during the coming session a large addendum. The assistants are reported to have proved themselves worthy of a good library by the advantage they have taken of the, as yet, necessarily small one. Another source of interest and instruction has been the microscope, for which the Association is indebted to the kindness of Messrs. Evans, Sons, and Co., of Liverpool. The President, Mr. John C. Hunter, has kindly given both time and talent in mounting a very large number of interesting objects. Thirty-seven members have availed themselves of the tutorial class, and the Committee is confident that it will enable many to pass the Preliminary examination. The chemistry class under the supervision of Professor Dittmar has also been a decided success, twenty members having enrolled themselves for the same. A botanical class has just been formed, which is conducted by William Keddie, Esq., F.R.S.E. This class has every prospect of being successful, twenty-three members having already joined it. During the past year six members of the Association have passed the Preliminary examination, six have passed the Minor examination, and two the Major examination; not a few of these have passed with honours. The Committee report that in the arranging and getting up of the syllabus no difficulty was experienced. The Committee regret, however, that so little has been done in a matter of such vital importance as early closing, although the Association has discussed the matter again and again. The several committees appointed to call on refractory members have had little or no success to chronicle. The general statement is that the contingencies of their businesses and their pockets will not allow them to close at the same time as their more liberal-minded and large-hearted neighbours. The Committee, however, is confident that early closing will never be brought about by framing and moving compulsory motions respecting office-bearers and members. The Committee closes its annual report by acknowledging some handsome donations received from members of the Association, amongst which were the President's donations of microscopic objects and books, and Mr. R. S. Neilson's donation of books, including 'Spon's Workshop Receipts,' 'Attfield's Chemistry,' and 'Green's Botanical Dictionary,' 2 vols.

Mr. Simpson moved that the report be adopted, which was seconded by Mr. William De Nance, and unanimously agreed to.

A few more members were then enrolled for the botanical class.

The Secretary (Mr. John Foster) intimated that the new President of the Senior Section of the Association (Mr. William Greig, New Apothecaries' Co.) had presented three guineas to purchase books for the most proficient in the several classes, which are about to terminate for the session. The Secretary was instructed to write and acknowledge Mr. Greig's generosity.

The election of office-bearers and Committee for next session then took place, which resulted in the following:—President, Mr. John C. Hunter, A.P.S. (re-elected); Vice-President, Mr. William MacKenzie, A.P.S.; Secretary, Mr. John Foster, A.P.S. (re-elected). Committee: Messrs. J. Fotheringham, W. De Nance, J. Bardsley, J. M. Nicol, R. K. Currie, and W. Wallace.

The Secretary proposed a vote of thanks to the retiring office-bearers, which was warmly responded to.

SUNDERLAND CHEMISTS' ASSOCIATION.

The annual meeting of the above Society was held on Wednesday evening, May 5th., Mr. Harrison Thompson in the chair.

The following officers were elected for the ensuing year:—President, Alderman Thompson; Secretary, Mr. J. J. Nicholson; Treasurer, Mr. R. Robinson. Council: Messrs. J. Harrison, H. Thompson, Nasbet, Lord, Chakman, Priestly, Mitchinson, Turnbull, Sayer, Sharpe, Clarke.

The following resolution was brought forward by Mr. J. Harrison, and unanimously agreed to—

> "That this Society being deeply impressed with the unequal state of the law by which Pharmaceutical Chemists are exempt from service on Juries, whilst Registered Chemists and Druggists, who discharge the same duties and incur equal responsibilities, enjoy no such exemption; desires to urge upon the Council of the Pharmaceutical Society the necessity of taking such steps as may tend to bring about a more equitable and satisfactory state of the law."

BRISTOL PHARMACEUTICAL ASSOCIATION.

A meeting of this Association was held on Friday, April 30, when a lecture "On Some of the Phenomena accompanying a Change of Physical State" was delivered by Mr. Thomas Wills, F.C.S. We shall take an early opportunity of printing the lecture in the *Pharmaceutical Journal.*

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, May 6, 1875. Dr. Odling, F.R.S., Vice-President, in the chair. After the ordinary business of the Society, Professor N. S. Maskelyne read a paper on "Andrewsite and Chalcosiderite," the former of which is a new mineral from Cornwall, named after Professor Andrews. There were also papers entitled "An Examination of Methods for Effecting the Quantitative Separation of Iron Sesquioxide, Alumina and Phosphoric Acid," by Dr. W. Flight, and "On Sodium Ethylthion-sulphate," by Mr. W. Ramsay. Mr. J. Williams, in his communication "On a Milligrade Thermometric Scale," proposes to substitute the freezing and boiling points of mercury for those of water, and to divide the scale into a thousand parts. Mr. C. Griffin exhibited and described some new gas furnaces, which are very economical and of great power. The meeting finally adjourned until the 20th May, when the following papers will be read:—1. "Note on Milk in Health and Disease," by Mr. A. Smee, jun.; 2. "The Effects of Pressure and Cold upon the Gaseous Products of the Distillation of Carbonaceous Shales," by Mr. J. J. Coleman; 3. "On Some Nova Scotia Triassic Trap Minerals," by Professor How; 4. "On Some Points in the Examination of Waters by the Ammonia Method," by Mr. W. H. Deering.

PARIS SOCIÉTÉ DE PHARMACIE.

A meeting of the above Society was held on Wednesday, April 7, under the presidency of M. Planchon. Amongst the correspondence read was (1) a note from M. Stanislas Martin, on paper made from the sugar cane, accompanied by a specimen of the paper; (2) a note from M. Vidau, upon some new reactions of saccharine bodies; and (3) a note from M. Husson relative to the action of iodine upon different rhubarbs as a means of recognizing their quality and source.

The President announced the loss to the Society, by death, of M. Roucher, and invited M. Jeannel to read the discourse that he had pronounced over the tomb of their late colleague. M. Planchon also announced the death of Mr. D. Hanbury, which he described as being a loss to materia medica, the study of which had been facilitated by the numerous correspondents with whom Mr. Hanbury had maintained relations throughout the world.

Dr. De Vrij, who was present at the sitting, offered to the Society a specimen of a crystallizable resin obtained from *Podocarpus cupressina*. The resin is found only in aged trees; it is soluble in alcohol from which it crystallizes, slightly soluble in carbon bisulphide and melts at a temperature above 120° C. Dr. De Vrij quoted a memoir on this resin by M. Oudemans, who thought its origin went to support the theory that cellulose may be transformed into resin.

The Mixed Alkaloids of Red Bark.

Dr. De Vrij also presented to the Society a specimen of a product, which he said was esteemed in England and Holland, and consisted of a mixture of all the alkaloids extracted from red bark. He felt assured that such a mixture would be an excellent febrifuge.

M. Mialhe said that he had long held the same opinion.

To a question whether such a mixture had clearly defined characters, Dr. De Vrij replied: (1) That if the mixture be examined polarimetrically it is always found to be levogyre, in consequence of the predominance of cinchonidine; (2) that by making a hot concentrated solution of this mixture in alcohol slightly acidulated, a crystallization is obtained resembling sulphate of quinine, which would not take place if cinchonine were present in great quantity. The composition of the mixture was not constant.

MM. Baudrimont and Poggiale thought that the use of this product was not to be recommended, and that it was important to supply practitioners and patients with definite crystalline compounds like sulphate of quinine, the composition and purity of which could be recognized.

In reply to a question as to the kinds of red bark which were most suitable for use, Dr. De Vrij said that the Indian barks are preferable to those from America: the latter are always old, and it has been proved that when barks have arrived at the age of fourteen years they begin to be less rich in alkaloids than younger barks. Dr. De Vrij added that the Indian barks are rather brown than red, and that they acquire that colour only with time in consequence of the oxidation of the cinchotannic acid.

Preparation of Ethylene Perchloride.

M. Bourgoin described two new methods of preparing ethylene perchloride. By the first sesquichloride of carbon is dissolved with heat in double its weight of commercial aniline. The mixture is heated in a retort to 170° C., and the product, which distils slowly, is collected in a slightly cooled receiver. The action commences directly, and the liquid rapidly acquires a fine red colour. The distillate is ethylene perchloride containing aniline and sesquichloride of carbon in solution. In order to remove the latter body more aniline is added, and it is distilled at a temperature between 130° and 145° C.; the small quantity of aniline the product contains is easily removed by washing with dilute sulphuric acid, and it is dried over chloride of calcium. A strongly coloured liquid is left in the retort; it becomes solid on cooling and is aniline red. The ethylene perchloride prepared by this process, however, is not quite pure; the boiling point is not constant, although the greater part passes over at about 121° C.

M. Bourgoin states that he has obtained perfectly pure ethylene perchloride by treating well crystallized bromide of chlorethose with aniline. The reduction, which is more easy than with sesquichloride of carbon, is effected between 140° and 150° C. Hydrobromate of rosaniline remains in the retort. Prepared by this process ethylene perchloride has an ethereal odour, resembling that of chloroform. It boils exactly at 121° C, and has a density of 1·6595.

M. Vigier read a note upon the employment of glycerine in the preparation of pastes and pills.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Sale of Food and Drugs Bill.

On Tuesday the Committee on this Bill was resumed.

On Clause 21,

Mr. Muntz moved an amendment to the effect that the Justices before whom any complaint might be made under the Act might, upon the request of either party, cause any article of food or drug to be examined and analysed by the Inland Revenue Department, at Somerset House, whose certificate should be final.

Mr. Sclater-Booth could not accept the amendment, on the ground that it proposed to leave the final decision on questions of adulteration with the Department at Somerset House. That decision must rest with the Courts of Law. He was prepared to accept a proposal which had been placed upon the paper by the hon. member for Leicestershire, to the effect that the analyses might be conducted by persons appointed by the Commissioners of Inland Revenue, such persons to give certificates of the results to the Justices who were to decide the cases.

Sir H. Peek supported the amendment and quoted instances to show that many analyses conducted by local analysts were neither thorough nor sensible. The trading classes generally had no objection to inquiry, but they altogether objected to inquiry by incompetent men, which, as had been shown, too frequently resulted in both inconvenience and injustice. Personally, he should rather like to see all the analyses which might be necessary under the Act left to the Department at Somerset House. This would be a cheaper and more satisfactory course than the one proposed in the Bill. He quite agreed in the observation that if the chemists at Somerset House were made the sole analysts for the purposes of this Bill, it would largely prevent adulteration, while the ratepayers would be gainers by change. He did not think that it was fair that the same magistrates who in Petty Sessions had the appointment of the local analysts should afterwards at Quarter Sessions determine appeals from the reports of those persons. He should therefore support the amendment.

Dr. Cameron remarked that the scarcity of analysts now complained of was owing to the sudden demand for their services, which was the consequence of this sort of legislation. The *personnel* at the laboratory at Somerset House consisted of a principal, a deputy principal, eight permanent assistants, and eight temporary assistants, and it was impossible that such a staff could get through the enormous amount of work that was about to be thrown upon it under this Bill, and it could not be increased without great cost to the country.

Dr. Playfair said that in accepting the proposal that all the analyses should be conducted at Somerset House the Government were incurring considerable responsibility. He should wish to know what security the Government had that the assistants at Somerset House were properly qualified for the discharge of such important duties as were about to be thrown upon them by this Bill, because it was evident that the salaries they received were not such as the first chemists in the country would be entitled to. He, however, should not divide the Committee on the amendment.

Mr. Muntz withdrew his amendment in favour of that of the hon. member for Leicestershire.

Mr. Pell moved his amendment, which was as follows:—

"Clause 21, page 7, leave out line 6 and to end of clause and insert 'by persons to be appointed by the Commissioners of Inland Revenue, who shall thereupon make the analysis, and give a certificate to such Justices of the result of the analysis; and the expense of such analysis shall be paid by the complainant or the defendant as the Justices may by order direct.'"

Mr. Sclater-Booth would accept the amendment of the hon. member for Leicestershire, and said Her Majesty's Government were quite aware of the responsibility they were taking upon themselves by so doing.

Mr. Sullivan observed that the analyses conducted at Somerset House would command confidence.

Mr. Grantham thought cases might arise in which it would not be desirable to make either the complainant or the defendant pay the expense of the analysis.

Dr. Playfair moved that the amendment of the hon. member for South Leicestershire (Mr. Pell) be altered so as to make it begin with the words "by the chemical officers in the employment of the Inland Revenue."

After a brief conversation, the amendment was adopted with this alteration, and the Committee reported progress.

The House again went into Committee on this Bill on Thursday, when the amendment referring all disputed analyses to Somerset House was adopted as a substantive resolution. A considerable discussion took place in respect to the warranty referred to in Clause 24, and hopes were held out that at a future stage of the Bill a form of warranty would be sketched out. At the time of going to press the Committee had reached Clause 25, and was still sitting.

The following tabular arrangement will allow of a comparison of the clauses of the Sale of Food and Drugs Bill that have thus passed through Committee up to Clause 21 with the corresponding portion of the Bill as originally introduced under the title of the Adulteration of Food and Drugs Bill:—

As read a first time; the parts now altered or omitted printed in italic :—	As agreed to by the Committee; the new and altered parts printed in italic :—
7. No person shall sell any *article mixed for any of the purposes mentioned in the exceptions above set forth, if the matter mixed be more than is ordinarily required for the purpose, under a penalty of ten pounds. No person shall sell any article of food which by the usage of trade is sold in a mixed state, unless the ingredients shall be mixed in the proportions required by such usage, and no person shall sell any compounded drugs, except the same shall be compounded according to the prescription in writing submitted for that purpose, or in accordance with the regulations prescribed by the British Pharmacopœia issued by the General Medical Council, or with a basis to be laid down by the Pharmaceutical Society, or the Local Government Board, or the Privy Council, subject to a penalty of twenty pounds.*	6 [formerly 7.] No person shall sell any *compound article of food which is* not *composed of ingredients in accordance with the demand of the purchaser, under a penalty of twenty pounds. No person shall sell any compounded drugs except the same shall be compounded in accordance with the demand of the purchaser, or with the prescription in writing of a registered medical practitioner,* or with the *regulations prescribed by the British Pharmacopœia issued by the General Medical Council, or in Great Britain with a basis to be laid down by the Council of the Pharmaceutical Society of Great Britain or the Privy Council, or in accordance with the provisions of the Pharmacy Act,* 1868, *or in Ireland in accordance with the Act of the Session of the thirty-third and thirty-fourth of Victoria, chapter* 26, *under a penalty of twenty pounds.*
8. Provided that no person shall be guilty of *an offence* in respect of the sale of an article mixed with any ingredient not injurious to health, *whether the case may or may not fall within any of the above-mentioned exceptions*, if at the time of delivering such article he shall supply to the person receiving the same a notice *to the effect that the article is mixed, by a label written or printed on or with the article.*	7 [formerly 8.] Provided that no person shall be guilty of *any such* offence *as aforesaid* in respect of the sale of an article *of food or a drug* mixed with any *matter or* ingredient not injurious to health, *and not intended fraudulently to increase its bulk, weight, or measure*, if at the time of delivering such article he shall supply to the person receiving the same a notice, *by a label distinctly and legibly written or printed on or with the article, to the effect that the article is mixed.*
9. No person shall *knowingly*, and with the intent that the same may be sold in its altered state without notice, abstract from an article of food any part of it so as to affect injuriously its quality, substance, or nature, and no person shall knowingly sell any article so altered without making disclosure of the alteration, under a penalty in each case of ten pounds.	8 [formerly 9.] No person shall, with the intent that the same may be sold in its altered state without notice, abstract from an article of food any part of it so as to affect injuriously its quality, substance, or nature, and no person shall sell any article so altered without making disclosure of the alteration, under a penalty in each case of *twenty* pounds.

The first important alteration in clause 9 [formerly 10] is the addition of the following paragraphs:—

In Scotland the like powers shall be conferred and the like duties shall be imposed upon the Commissioners of

Supply at their ordinary meetings for counties, and the town councils for boroughs within their several jurisdictions; provided that one of Her Majesty's principal Secretaries of State in Scotland shall be substituted for the Local Government Board of England.

In Ireland the like powers and duties shall be conferred and imposed respectively upon the grand jury of every county, and town council of every borough; provided that the Local Government Board of Ireland shall be substituted for the Local Government Board of England.

11. The town council of any borough may agree that the analyst appointed by any *adjoining* borough or for the county in which the borough is situated, shall act for their borough during such time as the said Council shall think proper, and shall make due provision for the payment of his remuneration, and if such analyst shall consent, he shall during such time be the analyst for such borough for the purposes of this Act.

10 [formerly 11.] The town council of any borough may agree that the analyst appointed by any *neighbouring* borough or for the county in which the borough is situated, shall act for their borough during such time as the said council shall think proper, and shall make due provision for the payment of his remuneration, and if such analyst shall consent, he shall during such time be the analyst for such borough for the purposes of this Act.

12. Any purchaser of any article of food in any district, county, city, or borough where there is any analyst appointed under this or any Act hereby repealed shall be entitled, on payment to *the* analyst, or if there be no such analyst then acting for the district to the analyst of a *neighbouring district, of a sum not more than ten shillings and sixpence*, as shall be agreed upon between such person and the analyst, to have such article analysed by such analyst, and to receive from him a certificate of the result of his analysis.

11 [formerly 12]. Any purchaser of any article of food or of a drug in any *place being a* district, county, city, or borough where there is any analyst appointed under this or any Act hereby repealed shall be entitled, on payment to *such* analyst *of a sum not exceeding ten shillings and sixpence*, or if there be no such analyst then acting for such place, to the analyst of *another place, of such sum as may be* agreed upon between such person and the analyst, to have such article analysed by such analyst, and to receive from him a certificate of the result of his analysis.

Section 12 [formerly 13] relating to the officer named to obtain a sample of food or drug to submit to analyst remains unaltered.

14. The person purchasing any article with the intention of submitting the same to analysis shall, after the purchase shall have been completed, notify to the seller or his agent selling the article his intention to have the same analysed by the public analyst, and shall offer to divide the article into three parts to be then and there separated, and each part to be marked and sealed or fastened up in such manner as its nature will permit, and shall, if required to do so, deliver one of the parts to the seller or his agent. He shall afterwards retain one of the said parts for future comparison and submit the third part, if he deems it right to have the article analysed, to the analyst.

13 [formerly 14]. The person purchasing any article with the intention of submitting the same to analysis shall, after the purchase shall have been completed, *forthwith* notify to the seller or his agent selling the article his intention to have the same analysed by the public analyst, and shall offer to divide the article into three parts to be then and there separated, and each part to be marked and sealed or fastened up in such manner as its nature will permit, and shall, if required to do so, proceed accordingly, and shall deliver one of the parts to the seller or his agent. He shall afterwards retain one of the said parts for future comparison and submit the third part, if he deems it right to have the article analysed, to the analyst.

Clauses 14 and 15 [formerly 15 and 16] containing the provision when sample is not divided, and the provision for sending article to the analyst through the post-office, remain unaltered.

17. If any such officer, inspector, or constable, as above described, shall apply to purchase any article of food or any drug exposed to sale, and shall tender the price for the quantity which he shall require for the purpose of analysis, not being more than shall be reasonably requisite, and the person exposing the same for sale shall refuse to sell the same to such officer, inspector, or constable, such person shall be liable to a penalty of *five* pounds.

16 [formerly 17]. If any such officer, inspector, or constable, as above described, shall apply to purchase any article of food or any drug exposed to sale, *or on sale by retail on any premises or in any shop or stores*, and shall tender the price for the quantity which he shall require for the purpose of analysis, not being more than shall be reasonably requisite, and the person exposing the same for sale shall refuse to sell the same to such officer, inspector, or constable, such person shall be liable to a penalty of *ten* pounds.

Clause 17 [formerly 18] relating to the form of the certificate, remains unaltered.

19. Every analyst appointed under any Act hereby repealed or this Act shall report quarterly to the authority appointing him the number of articles analysed by him under this Act during the foregoing quarter, and shall specify the result of each analysis, and such report shall be read at the next meeting of the authority appointing such analyst.

18 [formerly 19]. Every analyst appointed under any Act hereby repealed or this Act shall report quarterly to the authority appointing him the number of articles analysed by him under this Act during the foregoing quarter, and shall specify the result of each analysis, *and the sum paid to him in respect thereof*, and such report shall be read at the next meeting of the authority appointing such analyst, *and every such authority shall annually transmit to the Local Government Board at such time and in such form as the Board shall direct, a certified copy of the number of articles analysed.*

Proceedings against Offenders.

20. When the analyst having analysed any article shall have given his certificate of the result, from which it may appear that an offence against some one of the provisions of this Act has been committed, the person causing the analysis to be made may take proceedings for the recovery of the penalty herein imposed for such offence, before any justices having jurisdiction in the place where the article or drug sold was actually delivered to the purchaser, in a summary manner. Every penalty imposed by

Proceedings against Offenders.

19 [formerly 20]. When the analyst having analysed any article shall have given his certificate of the result, from which it may appear that an offence against some one of the provisions of this Act had been committed, the person causing the analysis to be made may take proceeding for the recovery of the penalty herein imposed for such offence, before any justices *in petty sessions* assembled having jurisdiction in the place where the article or drug sold was actually delivered to the purchaser, in a sum

this Act shall be recovered in the manner prescribed by 11 and 12 Vict. c. 43, and may be mitigated according to the judgment of the justices.

mary manner. Every penalty imposed by this Act shall be recovered in England in the manner prescribed by the eleventh and twelfth of Victoria, chapter forty-three. *In Ireland such penalties and proceedings shall be recoverable, and may be taken with respect to the police district of Dublin metropolis, subject and according to the provisions of any Act regulating the powers and duties of justices of the peace for such district, or of the police of such district; and with respect to the other parts of Ireland, before a justice or justices of the peace sitting in petty sessions, subject and according to the provisions of the Petty Sessions (Ireland) Act, 1851, and any Act amending the same.* Every penalty herein imposed may be reduced or mitigated according to the judgment of the justices.

Clause 20 [formerly 21] which provides that the certificate of the analyst shall be *primâ facie* evidence for the prosecution, that the analyst shall be produced if required, and that the defendant and his wife may be examined, remains unaltered.

22. The justices before whom any complaint may be made under this Act may, upon the request of either party, in their discretion cause any article of food or drug to be examined and analysed by *the analyst of an adjoining district, who shall thereupon make the analysis as if he were applied to by any officer in his district, and may be required to attend to give evidence at the hearing of the case; and the expense of such examination, analysis, and attendance shall be deemed part of the expenses of executing this Act, unless the justices order the same to be paid by the complainant or the defendant.*

21 [formerly 22.] The justices before whom any complaint may be made under this Act may, upon the request of either party, in their discretion cause any article of food or drug to be examined and analysed by *the chemical officers in the employment of the Commissioners of the Inland Revenue Department, who shall thereupon make the analysis and give a certificate to such justices of the result of the analysis, and the expense of such analysis shall be paid by the complainant or the defendant as the justices may by order direct.*

Censure of a Druggist.

An inquest has been held by the City Coroner at Manchester on the body of Matilda Hardy, aged 10 months. The mother said that on Saturday night the deceased "seemed to have a cold," and would not take its food, and on Monday morning, "when it was a little worse," she took it to Mr. Holt, druggist, Deansgate. Mr. Holt said that the child had a severe cold, and he told witness to apply mustard and meal as poultices on the child's chest. The poultices had no effect whatever. Witness also received from Mr. Holt a bottle of medicine, with directions to give the child a spoonful every three hours, which she did. On Tuesday morning, at seven o'clock the child had several fits, and it died at eight o'clock. Mr. Holt saw the child, and after the death witness went for a certificate. He told his assistant to "write a paper out." The certificate upon which "Mr. Holt wrote something" was not ready till night, and witness's husband took it to the registrar.

Mr. G. W. Pettinger, surgeon, of 93, Great Jackson Street, who had made a *post-mortem* examination, said that death was caused by inflammation of the lungs, aggravated by want of medical aid. "The majority of such cases might be cured if taken earlier." The medicine produced seemed to be paregoric, and would be an improper medicine. The tendency of the doses given would be to increase the inflammation, and not to diminish it. The following verdict was returned:—"Died from inflammation of the lungs, aggravated by want of medical aid." The jury censured the druggist for his treatment of the deceased, and for giving the certificate in another person's name.—*Manchester Courier.*

Review.

The Science of Disinfection. By John Dougall, M.D Glasgow: James Maclehose. 1875.

Under the title of "The Science of Disinfection." Dr. Dougall has published a paper which he read before the Health Department of the Social Science Congress, at Glasgow, in 1874.

This little *brochure* of fifteen pages will be read with interest and profit by those who have formed no distinct notions regarding *disinfection, antiseption,* and *deodorization.* The author explains the difference between fermentation and putrefaction, and describes a series of experiments undertaken with the object of determining the effects of mineral acids, caustic alkalies, and carbolic acid, on solutions of organic matters. The substances selected for experiment were vaccine lymph and an aqueous solution of fresh beef juice, and Dr. Dougall has satisfied himself that the action of strong mineral acids is better in a hygienic sense than the fermentative action, and that fermentation is better again than antiseption.

As the author's experiments show that vaccinine is unaltered by carbolic acid, and as vaccinine is inimical to varioline, he argues that varioline would also be unaltered by carbolic acid, and if so, that there is then "a strong presumption that all zymotic poisons will, under the same circumstances, remain active; and not only so, but that carbolic acid rather antisepts—rather preserves than destroys—their infecting powers."

Dr. Dougall sums up the inferences to be deduced from his experiments in his concluding paragraphs, to which we refer our readers.

Notes and Queries.

[435]. CEMENT FOR COMPOSITION MORTARS.—As there is perhaps quite as much in the manner of effecting a joint as in the cement, the following hints may be serviceable:—

Scrub the fractured parts with a hot solution of soda, afterwards with clean hot water to remove the soda; this will give a pure surface for cement of any kind to adhere to.

Note.—If any radiating cracks remain in the mortar break them out, minding to save every bit; it is of no use to piece a mortar and leave it with a cracked sound, as it would certainly break out in use.

Place all the pieces in a warm oven (not too hot).

We place a bottle of the "coaguline" to liquify (you will pardon us if we say it is the best cement we know), and also a mixture, in equal parts, of fresh, fine plaster of Paris and powdered quicklime in a galipot in the oven to warm.

When all are of a suitable temperature, with a small spatula made from a slip of wood we mix the cement and lime powder to an easy paste, unite the pieces promptly as they best come together, squeezing out as much of the cement as possible, and testing with the finger nail by passing it over the joint that each is in its original position; now bandage tightly up, invert on a flat surface, put a 56 lb. weight or two on it, and leave for a day. Then place in a warm dry place (as on a mantelshelf) for a time, say a week, and afterwards bring into use.

We have had a No. 12 mortar, broken in five pieces, put together in this way which has been in constant use over seven years; being now unsound it is about to be restored.—T. K.

---

[438]. MICROSCOPIC EXAMINATION OF STARCHES.—I should recommend your correspondent to retain, unmounted, his specimens of the different starches, and when any one of them is required for comparative examination, or for study under the microscope, to use, as a medium, a small quantity of water, or any other fluid more suitable. I have not yet met with a medium for the permanent mounting of starch grains that yields perfectly satisfactory results, and, in addition, there are great difficulties as regards the cell, not yet fully surmounted.

The following fluid, as a medium for the temporary examination of starch grains, I have found very convenient and may be kept for any reasonable length of time:—

Saturate Distilled Water with Creosote, and take of the Filtered Solution	ℨv.
Spirit of Wine	ℨiss.
Glycerine	ℨiss.

Mix.

Water alone may be used, but it does not take to the glass plate so readily as this fluid, and if the examination in water be prolonged the granules tumble into heaps very inconveniently.

Not only the form of the granule, the shape and position of the hilum, but equally the lamination, form important points in the determination of a starch granule, and it will be found that the presence of a little glycerine in the medium makes the lamination more decided.

If starches be required for examination by polarized light, turpentine as a medium may be used, and if for a permanent mount, Canada balsam.

The result of investigations on some samples of Natal arrowroot will shortly be noticed.—THOMAS GREENISH.

Obituary.

Notice has been received of the death of the following:—

On the 15th March, 1875, Mr. Thomas Davison Wilson, Chemist and Druggist, of Newcastle-on-Tyne, aged 26.

On the 24th March, 1875, Mr. Thomas Williams, Chemist and Druggist, of Penrhyn, Mon., aged 57.

On the 7th April, 1875, Mr. William Dengate, Chemist and Druggist, of New Shoreham, aged 63.

On the 28th April, 1875, Mr. William Augustus Raynes, Chemist and Druggist, of Bethnal Green, aged 64.

On the 30th April, 1875, Mr. George Henry Ellis, Pharmaceutical Chemist, of Finsbury Pavement, London, aged 74. Mr. Ellis had been a Member of the Pharmaceutical Society since 1849.

THE GLASGOW MEMORIAL.

Sir,—One would have thought that your correspondent "Scotus," who, in his first letter, talks of the "wonderful logic running through the whole" of the Glasgow memorial, would have taken care to be himself logical. That he is not so, particularly in his letter on the scarcity of assistants, I would venture, with your indulgence, to show. At the outset, "Scotus" proceeds on the assumption that if he can prove that the scarcity of assistants is due to a cause other than the examinations, he will also disprove the assertion that that scarcity is owing to "the regulations laid down for conducting the examinations." Need I say that a more fallacious and illogical assumption it would be difficult to make? Does "Scotus," for a moment, imagine that a consequent must have only one antecedent—that one effect has one and only one cause? If such is his idea he is to be pitied. If it is not, then his whole letter is a blunder, seeing it neither proves, nor can prove, that for which it was written. Your correspondent has spent, I had almost said wasted, much time in endeavouring to show what everyone knew before, that, by the increased prosperity of the country, some trades were enriched in respect of followers, and others, notably the drug trade, were impoverished. The facts "Scotus" has stated about this and its influence on our own trade, both in respect of the number of its followers and of their efficiency and intelligence, are undeniable. Had "Scotus" confined himself to the statement of these obvious facts, and had he drawn, as his conclusion, that these were one of the causes of the scarcity and inferiority of assistants, his remarks would have been harmless. Your correspondent, however, has gone further, and has implied that not only has he given a cause, but the cause, and the only cause, and has therefore excluded altogether the possibility of the examinations having the same effect. Now, Sir, I maintain that this inference is, not only utterly illogical and unwarrantable, but also utterly false and unsound. I do not, like "Scotus," declare that there is only one cause for the scarcity of assistants; but, on the contrary, I hold there may be many. It can, however, be indubitably proved that the examinations that have at the present time to be passed are not only one of these causes, but a very important one. "Scotus" must have been exceedingly unfortunate in his choice of acquaintances, if it is after studying human nature, as displayed in them, that he has come to the conclusion that when a man decides what trade to follow, he does so merely from considering how much that trade will bring him in £ *s. d.* Let him study human nature from a higher platform than he has hitherto done, and he will find other motives than these influencing a man. It is acknowledged by everyone that, in spite of not very high wages, and very long hours, the drug trade has inducements which others have not. The position of a druggist, even at 20*s.* per week is above that of the bricklayer at 35*s.* To ignore this fact is to ignore truth, either ignorantly or wantonly. It is here the examinations come in, with what result is well known. The man who would forego the few shillings extra per week, when he considers the higher position he would obtain as a druggist, is yet deterred from entering the drug trade by the thought of these examinations, which, in his mind, assume gigantic proportions. Many men, who consider that the advantages of a higher social position make up for the smallness of the salary, yet consider that salary (otherwise large enough) too small for the trouble and expense accruing from the necessity of having to pass two or three examinations. While, I doubt not, many leave the trade, and others refuse to join it, from the smallness of the salary and the long hours, I am persuaded that an incredibly larger number are frightened out of it by these bugbears—examinations. These are facts which are indisputable, and can be proved any day, and to any extent. So that, in this respect, the grounds of objection "Scotus" and others urge against the Glasgow memorial are, in reality, *nil*. Nor is this a mere theory extemporized for the occasion. It will be found to be the only explanation that will apply universally. Nor is it an argument against it to say that many go in for the medical examinations, which are very much harder, and to which no objections are made. This was urged in one of the letters on the present subject,—and very unwisely. It must be remembered that the person who obtains his diploma and permission to practise has unlimited means at his command for more than compensating himself for his past trouble, and for raising himself to a position much higher than that to which the mere druggist can aspire. By these considerations he is led to undergo the examinations, whereas, in the case of the druggist, the advantages are not such as to repay him for his previous extra labour. I trust I have said enough to show that the scarcity of assistants is not due solely, as "Scotus" would affirm, to little wages and long hours, but to the present regulations concerning examinations as well. Thus, on this score at any rate, if the memorial is not to be supported, it cannot at least be condemned.

With regard to the large number of "doctors' shops," I would only say let druggists beware lest, in trying to abolish these they are not, in reality, knocking away their own footing. Many do not only assist in and keep druggists' shops, but also themselves study for medicine. They thus at once support themselves and obtain the wherewithal to conduct their studies. If "doctors' shops" are done away with, the means druggists now have of becoming members of a learned and honourable profession, and of making a competency while at the same time trying to obtain a practice, would be greatly diminished. Let druggists beware lest they imitate "vaulting ambition, which o'erleaps itself, and falls on the other side."

DIC VERA.

Glasgow, May 4, 1875.

Sir,—As Messrs. Currie and Fairlie have pointed out the delusion I laboured under in stating that Mr. Frazer must have gone to London with the intention of presenting a memorial without first having obtained a copy of it in Glasgow, I can now conceive of something more ridiculous than that—viz., that Mr. Frazer should have gone to London with the intention of supporting a memorial which he had never seen, especially when that cast discredit on his own conduct. It, however, strengthens the conviction that I have already expressed. As regards Mr. Fairlie's recommendation that "those who live in glass houses should not throw stones," it would be well if he reflected who commenced throwing the stones in this instance?

"Oh wad some power the giftie gi'e us,
To see oursel's as ithers see us!"

A quotation so beautifully expressed by Mr. Fairlie himself when he made his attack on the Edinburgh Council. I understand Mr. Fairlie's statement as proverbial, but if otherwise I can assure him, as far as the Glasgow assistants are concerned, their salaries are so infinitesimally small compared to the expense of a glass habitation that there is no chance of such an event, a more probable one being, "considering their long hours of labour, night-bell duty, etc.," a premature wooden encasement six feet underground, at the expense of the parochial board, from whence they will have little likelihood of pitching stones at the enlightened heads of the framers and supporters of the Glasgow memorial.

ASSISTANT.

May 11, 1875.

The Office of Public Analyst.

Sir,—On the plea that the office of public analyst if held by one "in trade" is unfair to others similarly engaged, Dr. Lyon Playfair proposes to disqualify such pharmacists from holding this position. In the face of the educational *status* of the pharmacist of the present day, and the thoroughly well-deserved encomiums of Mr. Sclater-Booth in the House as to the special qualifications of many such in office, no successful attempts can be made to discredit their ability to hold and to act; the argument then is mainly unfairness to others.

Some eighteen months' actual experience teaches me that no such unfairness has arisen; the great mass of the public care little for such distinctions; the marked improvement in the therapeutic value of medicines is due to the high education of this generation of pharmacists and has long since destroyed the idea that a special talent in medicinal preparations is illustrated by a few vendors only. Couple with this the fact that simple "drug-selling," as applied to the pharmacists of 1875, is as much an anachronism as an analyst of a bygone generation. What will be the result? An attempt to swamp the borough by a county interest in the appointment of future analysts has failed, and the value of local administration been fully recognized, but the value of the pharmacist's skill is to be stultified by a theory of unfairness. Thus many districts will go unrepresented.

The supply of analysts is regulated, like most things, by the demand; and as we are told science tendeth to clothe in rags, the practice of analytical chemistry alone is but an out-of-elbow sort of trade; the value of its association with pharmacy is recognized as means to the end of most men's labour.

I regard this motion in the light of a side wind levelled at the possible increase in the ranks of public analysts by skilled pharmacists, many of whom have laboured long and diligently to acquire that knowledge which, if we may believe certificates given to many medical aspirants for the office by some eminent professors of chemistry, may be acquired in a short term of ten lessons at one guinea per lesson.

EDWARD MOORE.

Pharm. Chemist, Public Analyst, Brighton and East Sussex.

Saxifraga Tridactyles amongst the Carnivora.

Sir,—Do you know the plant perched "in the crannied wall," barely three inches high, with leaves a quarter of an inch across? It scarcely looks like one of the raptores. Just imagine a bluebottle being strangled by it! Why the fly, if he were only a vegetarian, would quickly turn the tables. Besides, the plant in question is not noted for its wan, squalid leaves. The colour is due to its situation (witness many of our wall plants). I have gathered it myself on a damp hedgebank, bright and green, but still dotted with the red glands. Would some "advanced believer" kindly oblige me with the alimentary canal dissected from a Pinguicula, or the digestive organs of a Drosera for the microscope? I know we constantly find flies and such small deer dead in the embrace of their slimy, hairy glands, so we do in the bells of campanulas and in many others. The flies look dried up too, an appearance with which probably the summer's day has had somewhat to do, and not of necessity referable to the blood-sucking propensities of the plants. I know I may be very heretical, but did anyone ever observe a plant look any further advanced after refreshing on an unfortunate fly?

BOTANIST.

Norwich.

W. H. Kerr.—We are not aware that an authorized formula for the preparation you refer to has been published.

G. C. Druce.—(1) The plants sent are hybrids, between the cowslip and the primrose, and may be referred to *Primula vulgaris, β variabilis*, of Babington. The oxlip has shorter pedicels, a narrow calyx tube, and corolla tube not contracted at the mouth.

J. W.—Simple syrup flavoured with orange-flower water. The name "capillaire" was originally applied to a mucilaginous syrup, prepared by adding infusion of maidenhair to syrup, and flavouring with orange-flower water. For formula see Gray's 'Supplement,' p. 951.

"*Stamp.*"—All the labels sent would require a stamp.

"*A Minor.*"—If you refer to the reports of the discussions which took place at the time the Council decided upon the alteration in the conditions of the Bell Memorial Scholarship, you will find that the considerations to which you refer were not overlooked. See vol. iii., pp. 264 and 367.

A. S.—You are recommended to consult the agent, as the answer to your question would depend upon the manner in which the article is advertised.

"*Potio.*"—The coat of arms is the property of the Society in its corporate capacity, and neither Members nor Associates are entitled to use it as individuals.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. G. Mee, Mr. Hetherington, Mr. Lunn, Mr. J. Ince, Messrs. Sturge, Mr. Collier, Mr. Thresh, "An Examined A. P. S.," F. L. P.

ASAFŒTIDAS OF THE BOMBAY MARKET.

BY W. DYMOCK,

Professor of Materia Medica, Bombay.

Three distinct kinds of asafœtida are found in the Bombay drug market, and are known to dealers as Abushaheree Hing, Kandaharee Hing, and Hingra.

Of each of these drugs numerous qualities, more or less mixed or adulterated, are met with, but I purpose first to notice the unadulterated varieties only.

Abushaheree Hing is brought from the Persian Gulf ports, principally from Abushaher and Bunder Abbas; it is produced in Khorasan and Kirman by the *Ferula alliacea* of Boissier.

Specimens of the plant with the gum resin attached have been supplied to me through the kindness of Mr. Ardeshir Mihrban, of Yezd, and these specimens, which show both flowers and fruit, have, with plenty of mature seed, been forwarded to Mr. D. Hanbury, who has kindly taken the trouble of submitting them to Boissier, and has also sent packets of seed to the botanical gardens of Kew, Edinburgh, Oxford, Paris, St. Petersburg, Berne, Strassburg, Florence, Pisa, Naples, Palermo, Athens, and to botanical friends on the Mediterranean coast, in South Africa, and a few other places.

The specimens sent to Mr. Hanbury were collected near Yezd and Kirman, and were from three and a half to four feet in height, and the roots of some young plants which had never flowered were quite fresh when they arrived in Bombay, and exuded a thick milk when cut, which after a day or two became brown and translucent.

It is this drug alone which appears in the Bombay Custom returns as Hing or Asafœtida; all other kinds pass under the name of Hingra. Hing arrives here either in skins sewn up so as to form a flat oblong package, or in wooden boxes. It varies in appearance with age; when quite fresh it is soft and of the consistence of treacle, of a dull olive brown colour, and *purely garlic odour;* it is mixed with about an equal bulk of slices of the root. After having been kept some time the gum resin becomes hard and translucent, and of a yellowish brown colour.

In 1872-73, 3367 cwts. of this drug were imported from the Persian Gulf.

The method of collection has been described to me by Mr. Godrez Mihrban, of Yezd, and resembles the method of collecting Asafœtida, as described in the 'Amanitales,' except that the slices of root are mixed with the juice.

The price of the best Hing in Bombay is from twenty rupees to twenty-two rupees per maund of forty pounds.

Kandaharee Hing is a much rarer article and only occasionally appears in this market. It is brought from Kandahar packed in goat skins which are sewn up into an irregularly shaped oblong bag with the hair outside. This Asafœtida, when fresh, is in flaky pieces quite wet with essential oil, of a yellow colour, opalescent, with an odour like a mixture of garlic and oil of carraways. When kept for some time the gum resin loses its moisture and gradually becomes perfectly transparent and of a golden yellow colour; the odour also loses much of its aroma and approximates to that of the best Asafœtida of European commerce. Some packages of the latter which I have examined this season in Bombay I found to contain small portions of the moist opalescent gum mixed with the ordinary opaque kind, as well as with some fragments of an intermediate character, partly opaque and partly opalescent. I believe this drug will turn out to be the superior kind of Asafœtida noticed by Bellew as obtained from the node or leaf-bud at Kandahar. Kandaharee Hing is little known in Bombay, and is not retailed in the shops. It fetches about double the price of Abushaheree, and is not always obtainable; it is used as a condiment by wealthy people in Northern India.

Hingra or the Asafœtida of European commerce comes to Bombay in large quantities from two sources, viz., Southern Persia and Affghanistan. The Persian drug is met with in two forms, viz., in tears more or less agglutinated together, and secondly, as a soft, white, viscid mass. It arrives in skins or boxes, and is mostly exported to Europe, but some is used in India as a condiment or medicinally by the poorer classes. This gum resin is the Anghuzeh-i-Lari of the Persians, and there seems to be little doubt that it is the produce of Kämpfer's plant, whichever that may be. In price it varies much; the average for a good quality will be about ten rupees per forty pounds.

The Affghan drug differs somewhat from the Persian in appearance and odour. The best samples occur in small flat pieces or tears, to one side of which a few particles of sand are adherent as if the gum had run out into the ground near the root; these pieces are quite hard and dry, yellowish white externally, and display, when broken, a conchoidal milk-white surface. Many packages, as already mentioned, under Kandaharee Asafœtida, contain the opaque gum above described mixed with opalescent pieces and moist yellow particles together with much dirt; from such packages the best tears are removed, and the remainder pressed together forms second sort Asafœtida. Affghan Hingra is generally packed in skins, and the best sort will fetch about twelve rupees per maund of forty pounds.

The adulteration of Hing is carried on in Bombay. It is simply mixed with gum Arabic by treading the two together; the mixture is then packed up in skins so as to resemble genuine packages. Several qualities are prepared containing different proportions of gum.

Hingra is adulterated in Affghanistan and in Persia by the admixture of some white earthy material. The adulterated article which comes from Persia is in dirty white gritty masses and becomes very hard when kept. That from Affghanistan is of a brown colour and in small roundish masses, easily crushed into powder by pressure; according to Bellew, gypsum and flour are the adulterations.

A substance called Heera Hing is also met with here; it is obtained from the packages of Abushaheree Hing; many of these are quite liquid in the centre: the people who buy them for adulteration squeeze out this liquid portion and retail it at a high price as Heera Hing; it is of the consistence of treacle, and when dried becomes solid and translucent.

From the examination of a great many bales of fresh Hingra I have come to the conclusion that the Persian variety is produced by a different plant than the Affghanistan. Probably *Scorodosma fœtidum* will prove to be the source of the Persian and Falconer's *Narthex* of the Affghanistan kind.

OFFICIAL *VERSUS* OFFICINAL.

BY JOSEPH INCE.

Dr. Miller is reported in the Journal (May 8) to have read a paper before the Philadelphia College of Pharmacy entitled "Official and Officinal."

In it he disputes the correctness of Professor Attfield's adoption of the word official when applied to articles contained in the Pharmacopœia. The passage in the 'Manual of Chemistry,' which raised the question, is as follows:—

"The Pharmacopœia and all in it is official (*office* Fr. from L. *officium*, an office). There are many things which in pharmacy are *officinal* (Fr. from L. *officina*, a shop) but not official. To restrict the word *officinal*, first, to the contents of a pharmacist's shop, and, second, to that portion of the contents which is pharmacopœial is radically wrong, and should be avoided."

Dr. Miller's chief objections were, that the two words were both derived from the same root and the distinction was therefore arbitrary, that the term officinal had become established, and that its signification was well understood by all pharmacists.

The difficulty seems to depend on the want of an accurate application of the rules of etymology. That is official, in title or mode of preparation, which emanates from a legally constituted and recognized authority. That is officinal, a pharmaceutical expression, which is prepared according to the private judgment of a manufacturer and issued under the sanction of his *officina* or workshop.

Thus, for years Mr. Schacht's liquor bismuthi was an officinal remedy; since the production of the British Pharmacopœia it has become official. The statement that the two words being derived from the same root renders the modern distinction arbitrary or immaterial does not hold good.

In the first place, official and officinal are not immediately taken from the same root.

Officina, which gives *officinal*, is the contracted form of *opificina*, from *opifex*, the workman. It means a workshop—hence a laboratory—hence, in the third place, a shop, or place where manual labour is performed.

Officium, which gives *official*, is the contracted form of *opificium* the working or the work; and does not involve one solitary allusion to mechanical employment.

In the second place, not only may varied forms of words, drawn from one ultimate common source, be adopted with extreme advantage, but the *same* word, bearing totally different applications, may be traced to the same root; and it would be unsound in etymology to assimilate the meaning of either, or force them into convertible terms. Such a course would make havoc of the English language.

Let the word "office" stand as an illustration. Mr. Bremridge is the secretary of an official body, and the secretarial office is in Bloomsbury Square. It is surely not an arbitrary selection of a phrase to say in relation to his work that each member of the Council receives an official, not an officinal notice, when his attendance is desired. These summonses are authoritative, the delegated acts of authority, and consequently official. The names, the formulæ, and the instructions of the Pharmacopœia rest on the same foundation, and we are bound to use the fit expression. But a merchant in the City likewise keeps an office—the word is identical—yet his written directions to his clerks are not official, for they are of a private, personal character; nor are they officinal, for the latter bears only a medical signification. They are called *office* notices, and it is not arbitrary but strictly in accordance with the genius of the language to limit terms to their strict meanings, and to use their variations properly. To accomplish this thoroughly was Professor Attfield's motive in the construction of his book. He knew that to attach the word "official" to titles and preparations which come to us clothed with direct authority, was to follow the rules of common sense as well as those of grammar. Instead of keeping in the track of hereditary misconception a careful writer coming upon a doubtful word asks himself—what does this expression mean? and he is not compelled to perpetuate an error because it has passed unchallenged through the hands of successive authorship.

The credit of the initiation of the reform is due to the veteran author of the 'Companion to the British Pharmacopœia.'

It need not be pointed out to Dr. Miller that in French *l'officine* means the laboratory of a pharmacist, and his shop generally; that *les préparations officinales* are such as are found ready made in that *officine* as distinct from *préparations magistrales* which are made extemporaneously from the prescriptions of a physician.

The term "officinalis" still holds its place in botany because it is the Latin word; and the plants to which it is applied were those used in medicine and stored in the *officina* of the pharmacist.

Lastly, there is no wish in these remarks to stoop to special pleading.

It is at once conceded that up to a recent date the term officinal has been employed in the sense in which Dr. Miller would have it still retained; and that that use is fairly intelligible to pharmacists at the present time.

It is contended, on the other hand, that the old practice is open to serious question; that it cannot be defended fairly; and that the new nomenclature has solid arguments for its support.

PHARMACY IN ITS RELATION WITH MODERN MEDICINE.*

BY WILLIAM H. SPENCER, M.B., CANTAB., F.L.S.

(*Concluded from page* 912.)

Anon, the empirical, methodic, and eclectic schools were setting an example to the moderns which they were not slow to imitate—that of devouring one another. Galen appeared to set things right. He was born at Pergamos, in 132, studied medicine at the then centre of the learned world, Alexandria, and settled to practice in Rome, the then centre of the whole civilized world. Galen derives a good deal of his reputation from his own estimate of himself; he claimed to have removed all difficulties from the road that Hippocrates had opened, and to have shown the true way of treating disease. What that way was you shall judge from this specimen of how he treated fevers. He said that the morbific matter of fevers had to be "concocted," *i.e.*, to undergo a change whereby it was made fit to be eliminated from the body.—How true it is that history repeats itself! This change, so far as art was concerned, could be promoted by heat. Hence Galen shut his patient up in a room, closed him in with curtains, kept up a large fire, and gave the most heating medicines he could find. There is, however, a far greater interest for our purpose about Galen. He refers in his writings to the preparers and sellers of the materia medica, as a

* Read before the Bristol Pharmaceutical Association, March 25, 1875.

class distinct from those who practised medicine, under the names "Pharmacopolites" (φάρμακον, πωλέω) and "Ropopoles." It is probable that the origin of preparers and compounders of remedies is very ancient, for scattered through ancient writings are many references to several offices that are connected with this function exclusively. Thus we find in addition to Galen's class, the "Migmatopolai" (μίγματος, mixture, πωλέω, to sell), the "Pharmacopœus" (φάρμακον, a remedy, ποιέω to make), and the "Pharmacotriba" φάρμακον, and τρίβω, to draw out from). I think we may conclude that by Galen's time these various offices had become more or less merged in one, that of the Pharmacopolite, who may be regarded as the true ancestor of the modern apothecary.

For 800 years (from B.C. 400 to A.D. 400) the stream of medicine, pure as the knowledge of the times allowed—at least mixed with a goodly amount of knowledge derived from reason and experience—flowed on without obstacle in a straight and gradually improving course.

But by the beginning of the fifth century medicine had sunk to a very low ebb, or rather the stream was turned aside and diverted out of its straight course. Medicine was literally persecuted and banished from Europe, superstition and intolerance gaining the ascendant. The Nestorians, flying from persecution, found a home at Edessa, in Persia, and there they founded a school of medicine. Another branch of the Nestorians also settled in Arabia. Both schools became very celebratted, and it was in them that the Arabs first learned from h e Greeks that art and science they afterwards were so prominent in restoring and advancing.

Speaking of the Arabs, I shall recall to your minds a common belief that Arabia was the cradle of pharmacy. It is true that pharmacy owes more to the Arabs than to any other race or people; they first trained a special class to fulfil the functions of the pharmacopolites; they through alchemy started the now important department of pharmaceutical chemistry; their commerce enriched the materia medica with some of its choicest material. But the origin of pharmacy, and of the pharmacist or apothecary as distinct from the physician, dates from a period long anterior to that of Arab influence.

From the Nestorians and Arabs medical knowledge spread over Europe again, and three celebrated schools mark three centres whence the knowledge came—Bagdad, Cordova, and Salernum (this last the seat of Benedictine monks). In these three were deposited all the knowledge and science that had survived. For the rest, convents and monasteries were the places where relics of saints and martyrs were, so to speak, prepared and compounded for the use of the priest-physician, and be it said by the priest-physician himself. This stream of ignorance and superstition usurped the channel in which legitimate medicine should have flowed and ran on in no small force. But, thanks more especially to Salernum, the stream of medicine, though narrow, still flowed on. From this school emanated rules and enactments respecting both physicians and pharmacists—the distinction between the two was thoroughly confirmed,—and from this school also emanated the prototypes of our modern pharmacopœias. Thence, up to the twelfth century, the dispensatories were compiled by the physicians, and the government controlled those whose business it was to prepare drugs according to the formula of the dispensatories by strict regulations concerning adulteration and selling at too high a price. Subsequently, in the thirteenth century, the laws of Frederick II. of Germany confirmed these rules, clearly defining the distinction between the physician who used and the pharmacist who supplied remedial agencies. I need not tell you how much pharmacy owes to Germany, but I will point out here that one chief reason of this is the fact that in Germany the distinction that I have already shown to be based on necessity and reason has been thoroughly preserved.

Coming down to later times I may pass over the introduction of a distinct class of traders in drugs from Italy, and the gradual rise of the class we know as apothecaries in our own country, to a well-marked era which throws some light on the reciprocal relations I have spoken about.

In the middle of the 16th century the physicians began to need chemical remedies. Paracelsus was the pioneer in the introduction of chemical remedies into medicine, and Van Helmont afterwards carried on what Paracelsus had started. Hitherto alchemy had influenced medicine chiefly in calling forth much energetic and laborious effort to discover means for prolonging life. But when the body came to be looked at from the chemical side and disease came to be treated by chemical means, pharmacy reflected the influence. This, rather than alchemy, I take it, gave birth to pharmaceutical chemistry and eventually brought up a special class to pursue it. At the beginning of the 17th century, when the incorporation of the apothecaries took place, and the London Pharmacopœia was published, the relations between physician and pharmacist were clearly defined and reciprocal. The proportion and form of the compounds and simples used in medicine were fixed by law, and supervision over the apothecaries was given to the censors of the College of Physicians.

I must now refer to two important epochs, viz., 1618—1704 and 1704—1815. The events of these epochs influenced the state of medicine and pharmacy deeply, and to this day. In ancient and mediæval times the defective state of knowledge may be held to be a reason for unenlightened action and want of progress. But it is humiliating that in these later times, whilst such men as Harvey, Willis, Sydenham, Malphigi, and Glisson, in medicine, and Galileo, Newton, and Bacon, in science, were doing work such as no age has ever witnessed, medicine, as an art, was in our country brought into a state of degradation and opprobrium. Yet so it was; the light the men I have mentioned shed, illuminated a later age than that in which they lived.

After their incorporation in 1616, the apothecaries became a powerful body. The College of Physicians became a close corporation and failed to carry out the high and important functions with which it had been endowed. The apothecary was made use of to further the interest of the physican, he was gradually introduced into the sick-chamber, taking reports of cases to the physician, and carrying out his instructions as to treatment. Then the imperfect knowledge of disease, and the confidence he gained, operating with the dearth of educated physicians, brought the apothecary to apply remedies himself—to depart from his proper sphere and undertake the duties of the physician. Thus the apothecary became a rival of the physician and at the end of the seventeenth century the physicians resorted to an expedient to keep the apothecaries in check. The dispensaries arose and out of them a disgraceful contest. A celebrated law case settled matters in 1703. The decision of three courts of law was reversed by parliament, and the right of the apothecary to visit and prescribe as well as compound and sell, provided he took no fee, was affirmed. Consequently the apothecary measured his own worth and his patient's means in the quantity and price of the medicine he could induce the patient to take. The physicians had to assent or did assent to the system of polypharmacy that was thus occasioned, and acted accordingly. The departure of the apcthecary from his proper functions called up the retail chemist and druggist to compound and dispense. But this new class came into collision with the apothecaries; and then, be it said, men of education and high purpose amongst the apothecary-physicians (Mason, Good, Burrows—all afterwards members of the College of Physicians) could not brook the position in which they were placed, whence in 1815 the Apothecaries' Society was empowered by charter to grant licences for the joint practice of medicine and pharmacy. Thus, the distinction between physician and apothecary was obliterated, and the functions of the latter were transferred to an ill-educated and incompetent set of men. Much to their credit, this state of things was set about being remedied by the successors of this very set of men, and in 1840 the Pharmaceutical Society came into existence to undo the corruption that had arisen in the seventeenth and eighteenth centuries, and to restore to the apothecary his proper status and functions.

In all countries, except England, the functions of the physician and pharmacist have been kept distinct. Before each a high standard of attainments adapted to their respective duties has been set, which each has been bound to reach. So, instead of rivals, each has been the zealous and intelligent co-operator of the other in his separate and defined work. That England should no longer stand alone amongst nations in respect of the relations between her physicians and pharmacists, and consequently in respect of the relations between the state of her medicine and the state of her pharmacy, is now the aim of the work of men amongst you who are bound to carry out what they undertake.

I will then take it for granted that it is the function of the pharmacist to co-operate with the physician; the one following science and the development of his art to that mode of therapeutics thus pointed out, the other ready and able to supply all the needs created by this development.

Let me now attempt to put before you some thoughts as to the present state of medicine and the tendency of therapeutics with special reference to the state of pharmacy and the tendency of pharmacy for the future.

Medicine works in these times by scientific methods.

The questions asked are, *Why* does this or that take place? Why and in what way do such and such remedies produce their effects? The answer to these and such questions is not now, as formerly, sought in vague theory and philosophical guesses. The answer is sought, first: by patient observation and experiment and strict verification of the facts so obtained. The ultimate problem of medicine is to find means to remedy every remediable disease. The most direct way to attack this problem would be to try means or agents in actual cases and to note the results, and this way has been, and is, much employed. But, as I have already indicated, the great obstacle to true results in such a direct mode of attack is the plurality of causes and the intermixture of effects, both in the nature of disease and arising out of the many possible ways in which remedies may act. Modern medicine, therefore, attacks the problem in a roundabout way. Observation and experiment are carried on alike in health and in disease, and under every variety of conditions. I need only refer to the researches of Professor Bennett on the action of mercury on the biliary secretions, and to Dr. Harley's work upon the old vegetable neurotics, for illustrations of the application of this scientific method to the building up of a science of therapeutics in medicine. But facts are liable to be accepted without verification, and this points to an obstacle and a danger in the use of this method. I am afraid we have in medicine a considerable accumulation of unverified and worthless facts, and I would only now to you pharmacists convey a caution founded thereon. Do not assume too readily that needs founded on such facts are worth satisfying; be careful that the scientific work you do is demanded in consequence of *verified* therapeutic or other facts. In the second place, modern medicine works by generalization or induction. The inductions or laws of medicine are chiefly derived from other sciences; such as properly belong to medicine are derivative or empirical laws chiefly. Steady progress in observation and experiment, however, may be expected to produce true inductions of a scientific character, and thus we get a wide and hopeful field for the future. Then, a third method is inference and the application of laws to new cases—deduction. Medicine itself, I have said, contains but few generalizations obtained by induction, but it contains many derived from physics, chemistry and biology, of sufficient range to be good for deductive inference, at least for converting empirical into scientific laws. It is from physiology especially that such laws are derived, and these have had great influence in controlling and correcting empirical practice.

Such being the methods of modern medicine, it is unnecessary to argue that there is any obligation on the part of pharmacy to follow medicine and adopt the same methods. If medicine, working by these methods and gaining true knowledge, takes special precautions to render the knowledge true, the needs of medicine, at least their character, will correspond. It is, therefore, incumbent on pharmacy to be equally careful to use the same methods in order to produce work of the same character. There is abundant proof that pharmacy does use them now-a-days, and strictly within its own sphere. I will therefore content myself here with some thoughts of a practical kind that are suggested. The use of these methods multiplies the subjects for investigation and marks off districts and special fields in particular departments both of medicine and pharmacy. I think the practical upshot of this is that there is great advantage in relegating to pharmacy some work previously taken up by medicine. Let me instance the important work undertaken by Professor Tuson as to the action of digestive fluids on mineral remedies, for an illustration of what I mean. It has been a question whether medical men should study pharmacy or even the materia medica at all. Whether they should or not very much depends on what is meant by study. If it means such a knowledge only as will prevent errors and give an intelligent appreciation of what one's own business is, and what others have to do; then, I for one, should advocate the separation. In any view, there is no doubt that the present modes of medicine do place within the sphere of the pharmacist much work previously performed by others. The point for the pharmacist to consider then is, how he may best place himself and his successors in a position to undertake the work.

If I were to ask what intrinsic circumstances have most contributed to the present development of pharmacy, I should probably be referred to the development of the sciences physics and chemistry. There is no doubt about the fact that the great development of organic chemistry has influenced pharmacy to an immense extent. And as to physics, especially that department known as molecular physics, the influence has also been great. The properties of matter, those of gases in particular, have received much elucidation from the progress of physical research. And improved means of conducting physical research have influenced pharmacy. This would have been so had medicine developed in any direction. But the present state of medicine is due in great measure also to the influence of physics and chemistry, and herein we find new points of interest and a new relationship.

Medicine might be termed a department of applied biology, and we should therefore seek in biology those features which physics and chemistry have impressed on medicine. Biology is nothing more or less in the present day than organized physics and chemistry, for the great generalization of modern times, the laws of the correlation and conservation of force, have been carried up into biology and have made that science what it now is. These laws have in fact been made deductively the key to the phenomena of life. Biology has come to be the study of matter and force under special and complicated conditions, and that department of biology to which medicine is most closely affiliated—physiology, to wit—is now investigated from this point of view. The activities of living things are now investigated as due to the association of the same forces with the same matter that exist in the not-living world, only associated under new and special conditions of composition, form and situation.

Matter with its stored-up force is constantly entering the body; therein the matter undergoes change and the liberated force does work of a special kind, special because of the speciality of the conditions; both matter and force are finally returned to the inorganic world to be re-embodied, rearranged, and made fit to repeat the whole process again. Such is a statement in a general form of the prevailing physiological philosophy. The matter is investigated as a branch or as part of the science of chemistry, whilst force and its associations with matter are studied as a part of the science of physics. And, as in physics and chemistry, results to be of value must be expressed numerically, so in physiology it is aimed to express its results numerically too—the work done in the body is estimated in units. Thus the relations between food and muscular work, and through this the changes in muscular tissue when at work, are now expressed in definite numerical form. We have heat and its work also with its numerical equivalent, and we have chemical work and even nerve work similarly expressed.

If such is the conception of life-processes in health, what of disease? Well, modern pathology is modern physiology over again, the conditions being different and the results different. Let me quote from Professor Haughton to illustrate this: "The work due to animal heat would lift the body through a vertical height of six miles per day; .... an additional amount of work, equivalent to the body lifted though nearly one mile per day, is spent in maintaining its temperature at fever-heat." Now turn to therapeutics and see the influences on it. Dr. Gull says "The strength of modern therapeutics lies in the clearer perception than formerly of the great truth that diseases are but perverted life-processes." The facts of fever are now generalized in the statements "elevation of temperature" and increased excretion of urea and carbonic acid by the kidneys and lungs; thence we get all that knowledge summed up in the statement, increased metamorphosis and disintegration of the blood and tissues. And we get also a scientific and rational therapeutics. To the fever patient now, instead of Galen's heat and aids to concoction, we give fuel in the shape of wine and beef-tea—we seek to retard the desintegration of tissue—and we seek to reduce the temperature and consumption of the body by the external application of cold.

You will be paralysed with fear, in your anticipations for the future of pharmacy if I venture to suggest the probability of an extension of such an absence of need, *quâ* pharmacy, in the practice of medicine. Let me hasten then to reassure you.

Therapeutics is not all scientific and rational yet, and as it daily becomes more so, in some directions new needs that the pharmacist may satisfy come more and more into view. Even when most rational, it is not necessarily independent of the remedial agencies which the pharmacist may supply. Therapeutics is mostly empirical, *i.e.*, it depends on old remedies and upon experience as a reason for their use. But the tendency is to destroy empiricism, not by omitting the use of remedial agencies, but by resolving empirical laws into secondary and scientific laws, finding out why our practice succeeds and why it is confirmed by experience. The method of observation and experiment avails here especially and is largely prosecuted at the present day. A great need is thereby created, and the obligation to satisfy it rests upon the pharmacists. In accordance with some principles I laid down early in this paper, precise knowledge of what the therapeutical observer uses is needed as one of the first conditions of the research. This is not wholly a matter that pure science is concerned with; as this kind of research grows the demand will necessarily arise for particular preparations, and much of the material advantage of pharmacy will depend on the ability to supply the demand. Closely connected with this special need is another arising out of the same tendency of medical practice. It is that the composition and quality of remedial agencies, whether used for purposes of research or otherwise, should be referable to known standards. Volumetric analysis and the balance are now used to determine the results of the action of medicines, and medicine needs more accurate standards than reference to the British Pharmacopœia affords. The solutions used in analysis to test the purity, and this be it observed is only a relative term, of medicinal preparations are titrated. Why not titrate or similarly provide constancy of composition in medicinal preparations with a view to accurate determinations of the results? I will give an illustration of these sort of needs out of my own experience. As some of you may know, I have recently been working upon the effects of a comparatively new remedy for rheumatism, trimethylamine. I desired to know what it was that I was using, but the pharmaceutical chemists seemed a little surprised at the precise character of the information I needed. I got readily enough the mode of manufacture, but further information I had to find for myself. One reason for this may have been that pure science does not pay. However, it turned out that a substance was manufactured which was not what it had been assumed to be, nor could I ascertain, unless I paid same one to perform the necessary work, the exact composition and nature of what had been used. Naturally, if precise knowledge of the composition of the remedy has not yet been supplied, it would be too much to expect that the composition should be referable to some scientific standards. And, in this case we have a remedy, with considerable empirical pretensions to efficacy, whereas a good deal of useless work was lately done by pharmacists in connection with a remedy for cancer—condurango—before it was found that its efficacy had not been tested, that its reputation was indeed founded on the vague ideas and imperfect observation of one or two men who lived a long way off. But it would be such a fine thing to get a specific for cancer!

Therapeutics is also largely chemical, and thus supplies abundant subordinate purposes to the pharmaceutical science and art. As our knowledge of the chemistry of the perverted life-processes extends, so will develop knowledge of how to cure by chemical agents. This certainly promises plenty of future work to pharmacy. That old nightmare of incompatibles, which has weighed heavily on the minds of many a student and practitioner, opens up also need in the direction of chemical pharmacy. Again, I want to give carbonate of lithium in solution, and I refer to the pharmacist accordingly. The solution by means of carbonic acid gas is too cumbersome for my purpose—then, says the pharmacist, give it in pill. Under such circumstances the physician must either turn pharmacist or leave things as they are.

And now, in conclusion. I have given you principles rather than rules, I have dealt with generalities rather than details, and this because I would rather give, if I may succeed, a direction to your thoughts than convey detailed information. To complete the matter let me give you one more thought that comes out of what has been said, and has affinity with some important work that is now exercising the pharmaceutical mind. What bearing has all this on the education of pharmacists? If it is the purpose of the art of pharmacy to supply the need of the physician, it will be supposed that he who has to supply these needs should at least be able to find them out and appreciate them. The time has gone by when medicine could dictatorially bid pharmacy provide this or that for her purposes, and in certain form, and call in the aid of the censors of the College of Physicians to keep the pharmacist up to the mark. There must be, I take it, some notion on the part of the pharmacist of that art whose needs he is expected to satisfy, as a condition of intelligent co-operation. How this is to be brought about and carried out I will not venture to suggest, but to dispose of possible objections I may make this remark. In proportion as you give any man a thorough knowledge of the purposes he has to fulfil will you ensure that he does not mistake the purposes of another art for those of his own; but you will complete the security by giving him some sound knowledge also of what those other purposes are and what they involve.

THE ACTION OF IODINE UPON RHUBARB.*

BY C. HUSSON.

When a specimen of rhubarb in lump is examined, the physical characters, described by Cauvet,† are nearly always sufficient for the purpose of recognizing the quality and source of the drug. When, however, the examination is made of a sample in powder, the physical characters are insufficient, and the chemical properties leave much in doubt. In this latter respect the author thinks it would be of service to place on record some observations as to the phenomena that occur when rhubarb is submitted to the action of tincture of iodine. Like nearly all vegetable substances, rhubarb is capable of taking up a considerable proportion of iodine. The causes of this absorption are numerous, and the alkaline salts take their part in the phenomenon; but it is incontestable that the organic matters are also concerned in it.

The test liquor used by the author was a tincture of iodine (1 in 40), added by means of a burette graduated to $\frac{1}{20}$ of a cubic centimetre. The experiments were made upon picked specimens, in which the physical characters were clearly recognized whilst whole, and which were afterwards reduced to a fine, but not impalpable powder. The method adopted for testing was to suspend 5 grams of powder in 125 grams of distilled water, which was afterwards evaporated in a porcelain capsule to one-half, with continual stirring. It was then poured without filtering into a white phial, and restored to the original volume, care being taken to wash the capsule with a little water to remove adhering particles. To this liquor, when cool, iodine was added, until it gave a blue colour with starch mucilage. As at the close of the operation it was difficult to recognize the starch reaction because the liquid was turbid, this was ascertained by removing a drop or two of the liquid by means of a glass rod from the phial and letting it fall on some starch mucilage placed in a porcelain plate.

China Rhubarb, flat variety.—The convex surface presented the white lines disposed in a delicate network, mentioned by Cauvet; the under surface also showed the stars indicated as characteristic. It crackled under the teeth, and was hard and compact. Five grams of the powder, treated by the above process, gave a beautiful yellow-brown decoction, which heated with the tincture—

Absorbed without changing colour . .	14 c.c.
Changed colour with	17 „
Became dirty green with	23 „
Gave freely a blue colour with starch with	25 „

Or after having neutralized 0·625 gram of iodine. Thus 100 grams of this rhubarb would absorb 12·50 grams of iodine.

If the decoction were allowed to stand after the operation it was remarked that the liquid portion separated with difficulty from the insoluble matters. At the end of twenty-four hours it formed two layers,—the upper of a dark brown colour, the lower of a greenish brown,—separated by a greenish blue line.

If instead of boiling the rhubarb it was allowed to macerate twenty-four hours in 100 grams distilled water, stirring it every hour for the first twelve hours, about one-half the quantity of iodine was absorbed.

Chinese Rhubarb, round variety.—This rhubarb presented the same white network as the preceding; the interior, although more porous, was far from being spongy. The absorbent power of this specimen was greater than the former, as the decoction did not give a blue colour with starch until it had neutralized 29 c.c. of tincture, or equal to 14·50 grams of iodine to the 100 grams of rhubarb. After standing the liquid separated into two layers; the upper of a fine yellow-brown colour, the lower of a rather dirty yellow.

It may be admitted that this rhubarb, having the same origin as the former, belonged to an older plant. The starch had become transformed, thus augmenting the porosity and absorbent power of the rhubarb. It follows that although less handsome than the preceding it is more active, provided that it has not become altered. The product obtained by simple maceration neutralized 7 grams of iodine per 100 grams of rhubarb, or about half the proportion neutralized by the decoction.

Russian Rhubarb.—The specimen experimented upon presented the characters indicated by Cauvet. The interior was of a dark yellow colour, veined at the centre in white and red. The colour of the decoction was a rather redder brown than the preceding. Upon the addition of the tincture of iodine it—

Changed colour with	10 c.c.
Became bottle green with	12 „
Became a deep greenish blue with . .	17 „
Gave a strong blue colour with starch mucilage with	20 „

Hence 100 grams of this rhubarb would neutralize 10 grams of iodine. Upon standing, the liquor quickly formed two layers; the upper layer was of a greenish yellow colour, the insoluble portion was greenish blue. The product of maceration absorbed 5·5 per cent. of iodine, or little more than half as much as the decoction.

French Indigenous Rhubarb.—The specimen used was a very fine one. The decoction neutralized 10 per cent. of iodine, or as much as the Russian rhubarb. It was distinguished from the other, however, by the phenomena which accompanied the absorption of the iodine. The first drops of the tincture upon coming into contact with the liquor coloured it blue immediately, which did not occur with the other rhubarbs. This colour disappeared quickly upon agitation. After adding of the tincture of iodine—

8 c.c. the liquor remained of a dull colour.
10 c.c. it acquired a bottle-green colour.
11 c.c. it acquired a blue-green colour.
12 c.c. it acquired a blue-black colour.
20 c.c. it blued starch strongly.

Upon standing, the liquor separated into two not very distinct layers; the upper being green, nearly black, the lower quite black. The product of maceration absorbed 5 per cent. of iodine.

The differences above indicated the author considers to be sufficiently distinct to assist in recognizing the nature of a rhubarb, whilst not neglecting known methods. He believes, in fact, that the greater the proportion of iodine neutralized before any change in the colour of the decoction is manifested, the more certainty there will be that a rhubarb is of good quality. On the contrary, the less the proportion of iodine required to produce a greenish tint in the liquid, and to give afterwards a blue-black residue, the poorer would be the quality of the rhubarb.

One practical consequence of these reactions, which the author points out, is the possibility of having a certain number of iodized preparations, in which the iodine is completely masked by the organic matter. Thus it would be easy to prepare an extract of rhubarb containing a considerable quantity of iodine, which would not be driven off from the combination under the influence of heat. He suggests the following formula for a syrup of iodized rhubarb, which would contain 5 grams of iodine per litre:—

Macerate for twenty-four hours, 100 grams of Chinese rhubarb, coarsely powdered, in 400 grams of water. Strain, press, and wash the residue with 100 grams of water. Filter so as to collect 400 grams of liquid. Add gradually a quantity of tincture containing 5 grams of iodine as concentrated as possible. Dissolve in it 800 grams of sugar, and afterwards strain.

---

* Abstract of a paper in *L'Union Pharmaceutique*, vol. xvi., p. 99.

† See PHARM. JOURN. [3], vol. ii., p. 1009.

THE IRISH PHARMACY BILL.

On Thursday a deputation from the Pharmaceutical Society of Great Britain waited on Sir Michael Hicks-Beach, Chief Secretary for Ireland, on the subject of this Bill, which stood for second reading on Monday next. The deputation consisted of the President and Vice-President of the Society, Messrs. R. Hampson, J. Williams, T. Greenish, C. Cracknell, J. Robbins, Cornelius Hanbury, Dr. Paul, Mr. Flux (the Solicitor), Mr. E. Bremridge (Secretary and Registrar), and Mr. R. Bremridge (Assistant Secretary and Deputy Registrar).

Mr. Flux, in stating the object of the deputation, said: I think I may say for this Pharmaceutical body that last year, when there was a Bill before Parliament which showed something like an acceptable scheme, the Society displayed the utmost readiness to assist Her Majesty's Government in passing a practical measure, and, in now offering some opposition to this Bill, it does so only in the discharge of what it considers a duty.

The Pharmaceutical Society was established in 1841, for (amongst other objects) the purpose of advancing chemistry and pharmacy, and promoting *an uniform* system of education of those who should practise the same and providing a fund for the relief of the distressed members and associates, and of their widows and orphans.

The Society has always been entirely self supporting.

In 1843 the Society was incorporated by Royal Charter, and empowered to appoint examiners and conduct (voluntary) examinations.

In 1852, the Pharmacy Act confirmed the charter, recognized the two examinations under it as being the Major and the Minor, created and protected the title "pharmaceutical chemist," authorized registers of the examined persons, placed on those registers as pharmaceutical chemists all then members of the Society, and entitled all who should thereafter pass the (voluntary) Major examination to be placed on that register.

In 1868, the Act to regulate the sale of poisons altered and amended the Pharmacy Act, 1852, created a register of and protected the title of "chemist and druggist," and entitled all pharmaceutical chemists and also all persons then in business as chemists and druggists, and all persons who had passed or should thereafter pass the Minor examination to be placed on the register of chemists and druggists, and enacted that the retailing, selling, and dispensing of poisons should be conducted only by persons on the register of "pharmaceutical chemists" and "chemists and druggists." The last mentioned Act made the appointment of examiners subject to the approbation of the Privy Council, and the conduct of the examinations subject to the presence of an officer appointed by the same Council. Thus there has arisen a recognized body of chemists and druggists, and within that class those exclusively entitled to the style "pharmaceutical chemists."

The Society continues to be a voluntary society, and all pharmaceutical chemists, and some chemists and druggists, are eligible for election to membership.

At the close of 1874 there were—

Registered Pharmaceutical Chemists and Chemists and Druggists	13,286
Registered persons who have passed the Preliminary examination	2000
Total . .	15,286

Of the above there were—

Members of the Pharmaceutical Society .	3374
Associates and Apprentices connected with the Society	1614
Total . . .	4988

within the corporate body.

The above-mentioned Society and the above-mentioned enactments operate within Great Britain only, and it appears that the limit has been of necessity, because there never has existed in Ireland a class of persons corresponding with the "chemists and druggists" of the said part of the United Kingdom.

The Irish Apothecaries' Acts have long been, and are now, in operation, so that all persons who in Ireland have kept open shop for the dispensing of medicines have been licentiates of the Irish Apothecaries' Company, and, virtually, medical practitioners.

In Ireland a system of local public dispensaries, conducted by medical practitioners, has existed; and there have been shops in which the sale of drugs and chemicals has been carried on in conjunction with the sale of groceries and other articles; but, in fact, the comparatively few shops in Ireland similar to the shops of the chemists and druggists in England have been conducted by licentiates of the Apothecaries' Company, or other medical practitioners, which facts would appear to give a reason for the absence of Irish co-operation in the foundation of, and progress of, the Pharmaceutical Society, and the limitation hitherto of that Society's sphere of operations to Great Britain.

The inconvenience of separate legislation relating to poisons so that one Act of Parliament applies to Ireland and the other Act applies to the remainder of the United Kingdom, appears by comparison of the Act to regulate the sale of poisons in Great Britain, 31 & 32 Vict. cap. 121, and the Act to regulate the sale of poisons (Ireland), passed July 14, 1870. Comparison of the earlier Act, sect. 17, and the schedules, together with the addition to schedules (pp. 160 and 162-5 of the Society's Calendar), with the latter Act, at pp. 306-7 of the same Calendar, will show that four classes of very dangerous poisons, which are in Part 1 of the schedule prevailing in Great Britain, are not poisons within the meaning of the Act operating in Ireland; and also that formalities necessary on the transmission of poisons by wholesale between the various parts of Great Britain (say from England to Scotland, or *vice versâ*) do not apply to similar transmissions of like poisons where those transmissions are from Great Britain to Ireland, or *vice versâ*.

In the parliamentary session of 1874, a Bill brought in by members representing Irish constituencies was laid before Parliament, and having for its object the extension to Ireland of the Pharmaceutical Society's operations, was considered by the Pharmaceutical Society, and that Society laid evidence before a select committee, disclosing its readiness to acquiesce in the legislation thus proposed, and showing that no dissatisfaction whatever with the Society or its operations prevailed in Scotland, and also that the Society was preparing to open its doors and its funds freely to Ireland, and establish in Dublin an examining Board similar to that which had always been maintained in Edinburgh.

The Society has a large establishment and accumulated fund for general purposes, raised mainly by subscription, an accumulated Benevolent Fund raised by subscription, and funds for scholarships and rewards raised exclusively by donation or subscription.

The operations of the Society involve an annual outlay exceeding £10,000.

The accumulated funds referred to comprise:—

General Fund in New Three Per Cents.	£18,000
Benevolent Fund in Consols	14,400
Bell Memorial Fund, Consols . , . .	2,050
Pereira Memorial Fund, Consols. . .	100
Secretary's Casual Relief Fund . . .	105
Hills Prize Fund	300
Total	£34,955

It was not and is not desired by the Pharmaceutical Society to establish a branch Society in Ireland, but on the contrary, that the Society's operations should be extended to Ireland, so that those resident in Ireland would be part of the general body and stand on a footing of perfect equality with those already within the Society and its operations.

The Society is prepared to change its name and become

"The Pharmaceutical Society," and as above suggested to admit all Irishmen who may acquire the proper status to participate in its Benevolent Fund and all other its benefits.

The report of the Parliamentary Committee (which Committee was almost exclusively composed of members representing Irish constituencies) was in favour of establishing in Ireland a separate Society, and the Bill now before Parliament is framed with that object and purports to establish a manner of reciprocity between the proposed Society and the existing one.

There is no existing Society or Society machinery in Ireland to be incorporated and utilized, but it would appear that the scheme of the Bill would introduce the novelty of creating by Act of Parliament a Society, appointing the President and Vice-President (each for life) and organizing a Board of Examiners.

The Bill does not disclose provision either present or future for the expenses of the Society, but contemplates provision for the expenses of examinations by way of fees payable by those who may be examined. The Bill then provides that all persons examined in Ireland (whether Irish or not) shall have the right of being placed on the existing registers of the Pharmaceutical Society of Great Britain, with a qualification to trade within Great Britain, and on such registration "shall be entitled to all the rights and privileges of pharmaceutical chemists under the existing Acts."

It is capable of demonstration that the fees payable by persons examined under the existing Pharmacy Acts do not exceed the moderate fees to the examiners and other expenses incident to the examinations, and as that is the case with the large number drawn from the area of England, Scotland and Wales, it appears a fair assumption that candidates drawn from the lesser area of Ireland will not provide funds adequate to the expenses of examinations in Ireland, and therefore, that unless the expenses of the proposed Society in Ireland be thrown upon the National Revenue, they will only be raised by a competition which shall induce the students of the other portions of the United Kingdom to pass their examinations in Dublin.

Thus the suggested reciprocity may assume the form of a competition in which the lesser body without traditions or resources may flood the proper area of operations of the older Society, and possibly destroy or hamper the important work of that Society.

The Bill now before Parliament contains in its preamble the following : "And whereas a great deficiency exists throughout Ireland of establishments and shops for the sale of medicines and compounding of prescriptions, and great inconvenience thereby arises to the public in many parts of the country."

The truth of the recital cannot be doubted, but the remedy proposed is not the extension to Ireland of the class or degree of chemists and druggists (that is of men fitted for the work of chemists and druggists) but is either to create in Ireland a new class which shall be equal to and rank with the highest degree of pharmacists in Great Britain, or to degrade the title pharmaceutical chemist, as it has been used in Great Britain, and confer the title upon those who, if examined within Great Britain, would pass on to the register of and be contented with the title of chemist and druggist.

Believing that the true mode of extending to Ireland the good which has been accomplished in Great Britain is to extend the operations of the existing body, and raise in Ireland the two grades, viz., pharmaceutical chemists and chemists and druggists, the Parliamentary Committee of the Society has passed in relation to the Bill resolutions as follows :—

1. That the Pharmaceutical Society of Great Britain regards as desirable an extension of the Pharmacy Acts to Ireland, so as to embrace Ireland within the operations of the Society, as Scotland has always been.
2. That the proposal made by the Pharmacy Bill now before Parliament for the establishment of a separate Society and examining body in Ireland, appears to be at variance with the policy of not multiplying examining bodies, and to be objectionable.
3. That the Society do oppose the principle of the present Bill.
4. That a deputation do wait upon Her Majesty's Chief Secretary for Ireland, and lay before him the resolutions of the Committee.

Thus with every desire to assist in the most liberal spirit the passing of a measure for the benefit of the whole country, it is deemed necessary to oppose the measure which has been introduced.

In further evidence of the desire referred to, this Society will prepare and submit for consideration a Bill, having for its object to provide one law for the whole kingdom, for regulating the trade of chemists and druggists, and the sale of poisons.

Since I have been in this building, my attention has been drawn to the fact that the laws under which the Medical Council now exists established a Council for the whole realm, and that Council has established a pharmacopœia which is known as the British Pharmacopœia, and operates throughout the three kingdoms, extinguishing the three separate pharmacopœias which formerly existed. Before the Act was passed establishing that Council, Parliament arrived at a resolution that it was undesirable to multiply examining bodies in medicine. Now this is a branch of medicine, and it would appear that the proposal to form a new examining body in Ireland is really opposed to that which would appear to be a proper and satisfactory course.

Sir Michael Hicks-Beach: Well, gentlemen, there is a very strong feeling in Ireland which was manifest in the Committee of last year, and of which I have had still further proof, that they would prefer a Pharmaceutical Society of their own, as they have a College of Surgeons and a College of Physicians of their own, to any union, so to speak, with the Pharmaceutical Society of Great Britain. It is impossible for the Government or for Parliament, I think, to ignore that feeling, and therefore I have introduced this Bill to carry out the Report of the Committee of last year, and I think that so far as regards the formation of a separate Society, that is a point of principle which I can hardly depart from. Your ground appears to me to be this, that the formation of a separate Society may interfere with your position in Great Britain.

The Vice-President : Quite so.

Sir M. Hicks-Beach : I should like to know precisely in what points it would do so. I see here you stated that the Bill provides that all persons examined in Ireland, whether Irish or not, should be allowed to be placed on the existing register, and shall be entitled to all the privileges and benefit attaching to pharmaceutical chemists under the existing Acts. You have stated to me certain rights and privileges which arise from participation in the funds of the Pharmaceutical Society which are, of course, to all intents and purposes their private funds, and in which I do not think that Irish pharmaceutical chemists, if such a body should be established, would have any claim to participate. If there is anything in the Bill which enables persons who may belong to an Irish Pharmaceutical Society to participate in your private funds and the advantages which you derive from being members of this Society, I shall be very happy to amend it. That is one point, but that is rather of a private nature. The public matter is of course with regard to keeping open shop, and there I think reciprocity is desirable—it is almost essential in fact. But that of course ought to be guarded by providing, if possible that the examinations, in both countries should be as nearly as possible similar, at any rate that there should not be a danger, if we can guard against it, that either in London, in Edinburgh, or in Dublin, any body should provide an examination of an inferior character with a view to improve its own position by attracting candidates to pass its examinations ; thus flooding other countries with inferior pharmacists. That is what you wish to guard against, I think?

The VICE-PRESIDENT: Quite so.

Sir M. HICKS-BEACH: In this Bill it is proposed by Clause 12 that all the regulations to be made by the Irish Pharmaceutical Society shall be subject to the approval of the Lord Lieutenant and the Privy Council in Ireland, and be laid before both Houses of Parliament. You are subject in the same way, are you not, to the English Privy Council?

Mr. FLUX: Yes; our bye-laws have to be submitted for approbation, and the name of each examiner as he is appointed or re-appointed is submitted for approval, and, of course, he has no office until his appointment is approved. Our examinations also are attended by a medical gentleman nominated by the Privy Council. Uniformity between the examiners in England and Scotland is practically accomplished in this way.

Sir M. HICKS-BEACH: Because the Privy Council extends to Scotland?

Mr. FLUX: Yes; what we are desirous of is uniformity in the examinations, and we see great difficulties about that if there are examinations over which we have no control whatever. For the purpose of securing uniformity between England and Scotland within the past year the two Boards of Examiners have visited each other, and I believe that even the officials appointed by the Privy Council interchanged visits so as to see that perfect equality and fairness prevailed. Then, again, the President and Vice-President of the entire Society are *ex officio* members of both bodies of examiners, and occasionally go to Scotland and see for themselves, whilst by having the control over the appointment of the examiners the Council take care that the examinations really are identical and conducted in a *bonâ fide* manner. If an examiner were to run cunningly in any shape or way he would not be reappointed, or he might even be removed. It is thought to be almost impossible to create an examining body outside of these forces which should maintain the integrity of the examinations. Even the title of pharmaceutical chemist is regarded as the private property of this body, but the Irishmen are proposing to adopt our title: they are not content to go on as apothecaries or chemists and druggists, but want to be known by a name which we have created for ourselves.

Sir M. HICKS-BEACH: That title does not extend to Ireland now.

Mr. FLUX: No; but they want to come from Ireland to England and appropriate to themselves that title. The impression entertained is this, that, a foreigner, if he comes to us with diplomas of any and every sort, must pass our examinations if he wants our qualifications, so if an Irishman, who is in that sense a foreigner, will insist on being a pharmaceutical chemist, he has only got to demonstrate his capacity by passing the examinations like any other person who might present himself. In the same way, our English people, if they went to Ireland and want to begin to trade there, must demonstrate their ability to pass an examination and submit to it in Dublin.

Sir M. HICKS-BEACH: I would simply throw this out as a suggestion. Supposing a power were given to you, and to the new society contemplated for Ireland, to make regulations for what may be called an *ad eundem* examination, subject to the approval of the Privy Council in each country, do you think that would be satisfactory?

Mr. FLUX: I can hardly say whether it would or not. In all probability the Irish would desire that they should have a similar voice, in the control of our examinations, which have had approbation here of nearly forty years.

Sir M. HICKS-BEACH: I said regulations subject to the control of the Privy Council in each country.

Mr. FLUX: It would be the Irish Privy Council in Ireland, and the English in England, and if we are to have any weight whatever in framing regulations for Ireland, the Irish body, when created, will say they ought to have a voice in the regulations for England.

Sir M. HICKS-BEACH: You rather misunderstood me. I suggested, and I wish this to be understood merely as a suggestion with a view to ascertain your opinion upon it, whether you will consider it a satisfactory opinion if you, as the Pharmaceutical Society of Great Britain and the intended Society in Ireland were enabled to frame regulations for examination *ad eundem* in their respective Societies, subject in each case to the control of the Privy Council of the country to which they belong.

Mr. FLUX: Such a suggestion has not been laid before us, so far as I know, but it shall be considered. One can hardly see how it would be a satisfaction to Ireland our having a voice in regulations which should operate with them without their having a voice in ours.

Mr. WILLIAMS: The mere framing of regulations, unless the Society had a control over the appointment of members of the Board of Examiners, would, I fancy, be of very little service. It is necessary to have that controlling power as we have in Scotland. We appoint the Board of Examiners there, though there is a local body in Scotland, whose duty it is to recommend the men to be appointed, and I believe we have never rejected anyone they have recommended. At the same time the appointment is in the Council of the Society as a whole, and unless we have the appointment as well as the mere power of drawing up regulations, I do not think we should have a real control over the examinations. The 18th clause of the Bill says every person registered as a pharmaceutical chemist in Ireland, is, upon application, without being obliged to pass a further examination, entitled to all the rights and privileges, and subject to all the liabilities of a pharmaceutical chemist in Great Britain; therefore he would be enabled to sit on the Council and to be President, and enjoy the privileges of the Benevolent Fund.

Sir M. HICKS-BEACH: I did not contemplate that those privileges should attach to the position. What was contemplated, I think, was this, the privilege of keeping open shop, which is quite another matter.

Mr. WILLIAMS: There, again, we are afraid—as he will possess the title of pharmaceutical chemist, which is our highest title, and is to be subject to only one examination, although that might contain all the points of our three—he would, probably not be so efficiently examined as our present men are. Our system is to have three examinations, Preliminary, Minor, and Major.

Sir M. HICKS-BEACH: You are assuming, what I do not admit, that the Irish Pharmaceutical Society would institute a lower class of examinations than you have.

Mr. WILLIAMS: Our theory is that it would.

Sir M. HICKS-BEACH: To go back to the suggestion I have already made—supposing these rights and privileges so far as keeping open shop is concerned, were strictly extended to all persons belonging to the Societies, having passed an examination in either country, except in cases where it might be considered necessary that there should be a further examination by the Society of the country in which the person wished to practise, leaving you or the Pharmaceutical Society of Ireland, as might be, the power of requiring persons coming from the other side and desirous of keeping open shop to pass some fresh examination—would not that meet your objection?

THE SOLICITOR-GENERAL FOR IRELAND: I think you hardly realize the suggestion of the Chief Secretary as regards the *ad eundem* degree. It would be for the Pharmaceutical Society in England to settle in the first place the conditions of the *ad eundem* examination for persons coming from Ireland; in the same way in order to practise in Ireland the Irish Society would have to settle the conditions of it; but in each case it would be subject to the control of the Privy Council in either country. Therefore, it is not likely the English Council would frame terms too easy for the Irish candidates, nor would this be likely to happen *vice versâ*.

Mr. Williams: Pharmaceutical chemists are rather the exception than the rule, and nine out of ten of those who keep open shop are chemists and druggists. You do not propose or offer in this Bill to make the trade reciprocal, but simply limit it to pharmaceutical chemists, our highest grade, who have passed the third, and more important examination. Therefore, the Bill is not really reciprocal, and as I imagine many of the places in Ireland you wish to supply with dispensing chemists or pharmaceutical chemists are not very large or important places, they would not afford a very good living for any man, and would possibly not attract the best men from England to settle in Ireland, though they might attract chemists and druggists, who are very numerous, something like 9,000 or 10,000. These are all excluded from reciprocity in this Bill.

Sir M. Hicks-Beach: I do not think it would be reciprocity if we included them, if our examinations were equally difficult for the degree of pharmaceutical chemist. It would be impossible to allow a chemist and druggist to come to Ireland and obtain all the privileges of a pharmaceutical chemist.

Mr. Flux: In Scotland last year only six persons presented themselves as candidates for the higher degree, and this consideration arises out of the observation just made—that if you examine only for the higher degree you will defeat the object of the Bill altogether; because the higher degree as it exists in this country, and as appears to be contemplated in Ireland, involves a greater amount of skill in pharmacy and chemistry than is required by those bodies who examine in medicine. Now your deficiency in Ireland at this moment arises from the fact that you only allow licentiates of the Apothecaries' Company to carry on business as chemists and druggists. When I was in Dublin last year, a physician explained to me that the cause of the dearth of chemists and druggists in Ireland was that young men had to prepare for such a high examination in order to obtain the degree of licentiate, that they preferred taking the little additional trouble which would secure to them a degree in medicine. But that trouble would not be equal to that necessary to pass our Major examination, and so acquire our degree of pharmaceutical chemist. Thus, if you only establish in Ireland, under this Bill, an examination which shall be stiffer than the existing examination in pharmacy and chemistry, you will provide no persons to carry on the business of chemist and druggist according to the necessity indicated in your preamble. If out of the whole of Scotland there were only six candidates you cannot expect any very considerable number in Ireland.

Mr. Hampson: We find from experience that many persons who pass the Major examination are educated beyond their calling, and they leave the business to become pure chemists, or to enter some other occupation. The majority of those in business pass the Minor examination for chemists and druggists.

Mr. Robbins: We also think that a person who is sufficiently educated to practise as a chemist and druggist in England, ought to be considered sufficiently educated to practise in like manner in Ireland.

Sir M. Hicks-Beach: Would you put that *vice versa*.

Mr. Flux: Certainly; if the test be the same.

Mr. Williams: It seems clear that a man who is competent to dispense medicine for English and Scotch people, is competent to dispense for Irish people. Our Minor examination declares a man competent to carry on business and to dispense medicines, but it does not declare him a scientific or highly qualified pharmacist.

Mr. Flux: It is as though you were to say that no man should practise surgery who had not passed the very highest degree.

Mr. Williams: We are afraid that England will be swamped by an influx of cheap and inefficient pharmaceutical chemists from the sister country. That is why we come here in the interests of our own body to call your attention to the matter. We have no objection in the abstract to a pharmaceutical society for Ireland; on the contrary, we would support such a thing.

Sir M. Hicks-Beach: You wish there should be some provision—that if Irish pharmaceutical chemists are allowed to practise as such in England, they should have passed a proper examination.

Mr. Williams: Exactly so.

Sir M. Hicks-Beach: If that is secured in any way, it does not much matter to you whether the Bill would provide for Ireland a sufficient number of such chemists or not.

Mr. Williams: No.

Mr. Hampson: But apart from the feeling which exists in Ireland, do you not think it undesirable to have a new body created, when there is one already in existence which is willing to do the work satisfactorily, and also to permit Irish members to sit on the Council, and to have all the privileges, and an equal share of representation, and so forth? Any scheme of a different kind seems to exclude all these points, and so produce a difficulty which does not exist at present.

Mr. Flux: If the control were left to the central body of course the examiners appointed to act in Dublin would be resident in Dublin; the Society would not be sending men over there from time to time to conduct the examinations. In Edinburgh they appoint gentlemen resident in Scotland, and the same would be done with regard to Ireland. I would also mention that I believe there is actually prepared by the Medical Council, or, at any rate, there is in contemplation, a measure for doing away with the great number of examining bodies in the various kingdoms, and providing for a uniform examination which should emanate from the central body.

The Solicitor-General for Ireland: It has been suggested that there is a great difference of opinion as to the propriety of doing so.

Mr. Flux: Not amongst the medical faculty, I believe.

Sir M. Hicks-Beach: Possibly not, but amongst those who have to be examined.

Mr. Flux: I believe it is found that an unduly large number of English students go down to Scotland to get their degrees, because they can do so with greater ease.

Sir M. Hicks-Beach: Well, gentlemen, I think perhaps the best plan will be for you to consider the suggestion I have made with regard to the *ad eundem* examinations, and that you should appoint, if you would, two or three of your body to see me again upon the subject. I can assure you I am only anxious that this Bill should benefit Ireland without interfering with you.

Mr. Flux: Would you allow me also to submit a bill which I have in draft for working out this difficulty according to the views of this Society? If you would consider the draft you would see the scheme in its entirety.

Sir M. Hicks-Beach: I have no objection, but I believe your views were fully put before the Committee last year, and were not accepted for the reasons I have stated.

Mr. Flux: At the same time I think it is really imperial legislation which we are fairly entitled to look for; not English, Scotch or Irish legislation, but legislation for the whole realm.

Sir M. Hicks-Beach: What you are entitled to is a Bill to carry out what is wanted in the best way.

The President: I would venture to throw out the suggestion that you should follow the plan we have adopted for so many years of having three examinations—Preliminary, Minor, and Major.

Sir M. Hicks-Beach: I will consider it, certainly.

The President: We understand you will not bring forward the Bill for second reading until we have seen you again.

Sir M. Hicks-Beach: Certainly. I shall not bring it forward on Monday next. But I shall be glad if you will see me again about it as soon as possible.

The deputation having thanked the Chief Secretary for his courtesy then withdrew.

The Pharmaceutical Journal.

SATURDAY, MAY 29, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE IRISH PHARMACY BILL.

THE greater the consideration bestowed upon the details of the Irish Pharmacy Bill now before Parliament, the more apparent it becomes that the Bill, so far from accomplishing a public good for the United Kingdom, can, at its best, produce a very limited benefit to Ireland and is pregnant only with mischief to the other portions of the United Kingdom.

We believe the Bill to be unique in proposing to create by Act of Parliament a Society, and to be singular in raising up for a proposed Society a President and Vice-President to hold office for life. The Bill is silent as to the monetary provisions clearly necessary for the machinery of a Society, and leaves the inference that the taxpayer is to be resorted to.

Whilst the Bill proclaims a great deficiency "throughout Ireland of establishments for the sale of medicines and compounding of prescriptions, that great inconvenience thereby arises," etc., the remedy proposed for the evil is that of creating pharmaceutical chemists, and not that of creating in Ireland or permitting there the very useful class of chemists and druggists. Thus the evil for which the Bill professes to provide a remedy is in a fair way of being perpetuated by it; for, as is known, the examinations in pharmaceutical and general chemistry necessary for the Major Examination (that being the examination requisite for the title "Pharmaceutical Chemist") are a more severe test of proficiency than the examinations in the same subjects which are required of candidates for degrees at the Apothecaries' Hall in Dublin. It will follow therefore in the future (as it has been in the past) that in Ireland the young men who have to prepare for the examinations requisite for keeping an open shop for compounding medicines will go on and complete the curriculum and become medical practitioners. Hence if the Bill became law the Irish Board of Examiners might be left in the difficulty of seeing young men continue to pass through the Apothecaries' Hall and become apothecaries, or of having to lower its own examinations so as to attract young men to them; and we do not perceive how young Irishmen are to be attracted by a proceeding which shall fail in attractiveness with the young men from the other portions of the Empire.

Reciprocity between the existing Society and the one proposed appears to be contemplated by the Bill, but that can only be of the kind possible between a large and vigorous body and a new creation; full reciprocity between the registered persons is not proposed. Persons who are pharmaceutical chemists on the existing Register are to have the privilege of going on the Irish Register and those who through the Irish Board may pass on to the Irish Register are to have the privilege of passing on to the existing Register, "and all the rights and privileges which those on that Register may possess;" but the important and numerous body of chemists and druggists not pharmaceutical chemists are to continue excluded from Ireland.

It is impossible to suppress the inquiry whether the promoters of the Bill are in good faith going for a measure in the interest of the United Kingdom, or for that which, in common phraseology, is known as a job. We hope for the former, feeling confident that, if the subject be impartially approached and considered, it will be seen that the true course is that which the existing body proffers in a liberal spirit; that, is the extension of itself over the area hitherto unoccupied (unoccupied only because the occupation has not been invited), and the welding of the great body of chemists and druggists throughout the United Kingdom into one Society without competing interests, with like sympathies and energies, and only one set of expenses.

The leading facts bearing upon the subject have been embodied in a paper, of which a print will be found at page 951, and to that we invite especial attention, regarding as possible, and indeed, probable, the necessity for every chemist and druggist giving individual consideration to the subject, and contributing the weight of his judgment to the matter in hand.

If Ireland is resolved to create a separate body, and have separate pharmaceutical legislation, there would appear to be no hardship in confining the effect of that legislation and the whole work and effect of the new body to Ireland; so that in the probable event of an Irish gentleman desiring to commence business in England as a chemist and druggist, he shall be left to demonstrate his capacity by the ordinary mode of passing the examination which his brethren in England are subjected to. A foreigner or colonist coming to England with the highest diplomas finds them of no avail; and if Irishmen will insist upon being, in a manner, foreigners within Great Britain, they should stand as foreigners, and not, on the one hand claim to isolate themselves, and on the other hand claim to invade a class of Britain.

DRUGGING OF ANIMALS.

On Monday last a Bill "to make the administration of poisonous drugs and compounds to horses and other animals a punishable offence," bearing the names of Sir John Astley, Mr. Chaplin, and Mr. Rowland Winn, was read a first time in the House of Commons. It will be remembered that at the meeting of the Council of the Pharmaceutical Society, on the 5th instant, a communication from Sir John Astley was read, suggesting that sulphuric, nitric, and hydrochloric acids, the sulphates of iron and copper, and several other articles of a similar character, should be placed in Part 1 of the Schedule of Poisons, a suggestion to which the Council did not feel able to accede. At the time of going to press the Bill had not yet been printed.

PHARMACY IN VICTORIA.

We regret to learn from the Report of the Council of the Pharmaceutical Society of Victoria, just received, that political complications and the illness of the late Chief Secretary, have balked the hopes of the pharmacists of that colony that before this time the Legislature would have granted them a Pharmacy Act. The nature of the Bill which the Society has urged the Government to bring forward has been described in a former volume* Another effort is, however, to be made, and, should the reply of the Government to a Deputation be favourable, the President of the Society will introduce the Bill, and it is hoped there will be little difficulty in carrying it through all its stages. We are not quite sure, however, that the members are so alive as they might be to the importance of active co-operation as an element of success in attaining the objects of such a Society. At any rate, although the balance at the bankers has increased, a praiseworthy attempt to establish "evening meetings" collapsed through the meagre attendance and languid interest taken in them.

If we may judge from its second annual report, the Victorian Chemists' Assistants' Association is more vigorous than the senior society. During last year it established a reading-room supplied with a selection from the leading pamphlets and periodicals relating to chemistry and pharmacy and the allied sciences published in England, America, France and Germany. The library already contains more than 150 volumes, and the nucleus of a museum has been formed. Chemistry classes have been successful and well attended, and several papers have been read before the Association by members. On the occasion of the second annual meeting, Baron Ferdinand Mueller, the Government Botanist, who has been elected patron, delivered an admirable lecture on the services rendered to science by pharmacists, which we hope to print in a future number.

* Vol. iii., p. 960.

HASTINGS AS A HEALTH RESORT.

Some short time since we noticed in a contemporary journal an inquiry as to the present sanitary condition of Hastings originating from the circumstance that a lady, who was desirous of taking change of air there, had been warned that small-pox was raging in the place. In referenee to this subject the report of Mr. Ashenden, the Medical Officer of Health for Hastings, has just reached us, in which it is stated that the inspector has reported to him five cases of infectious disease, and that measures have been taken to prevent their spread. He also states that in three instances notices were received by him reporting cases of infectious disease, which upon inquiry were found not to exist. Attention is particularly called to the small mortality from zymotic disease, there having been only seven deaths during the past quarter against thirty-three — chiefly from croup and whooping-cough—during the corresponding quarter of 1874. At the present time it is stated that there is an almost entire absence of any sickness of the same class.

A donation from Mr. Peter Williamson and a bequest by the late Professor Proctor have enabled the Board of Trustees of the Philadelphia College of Pharmacy to issue the regulations for the award of a scholarship and a prize in connection with the next and following courses of lectures at that institution. The "Peter Williamson Scholarship," consisting of matriculation and lecture tickets will be awarded annually to "one needy and deserving student," who may be elected by the Board of Trustees. "The Proctor Prize" will be annually awarded to the most meritorious graduate in pharmacy, provided that he, in the opinion of the Board, is deserving of such prize—which may consist of a medal, books, or instruments.

The subject which had been chosen by the Paris Academy of Medicine for the Orfila prize of the present year, 2000 francs in value, was "De l'aconitine et de l'aconit." Two memoirs were sent in, neither of which, however, has been deemed worthy of the prize, and it has been decided to continue the subject for the competition of 1876.

It will be interesting to botanists to learn that the new Judge, Mr. Nathaniel Lindley, Q.C., appointed to succeed Mr. Justice Huddlestone in the Court of Common Pleas, is the only son of the late Dr. Lindley.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The thirteenth and concluding meeting of the session was held at the Royal Institution, May 20, 1875. The President, Mr. A. H. Mason, F.C.S., in the chair.

After the routine business, Mr. E. Davies made some remarks on salicylic acid, explaining Kolbe's process for its manufacture from phenol, and exhibited a sample which he had made by that process. In his opinion the very slight solubility of salicylic acid in cold water, 1 in 1000, and its non-volatility were much against its value as an antiseptic.

The President exhibited the milligrade thermometric scale introduced by Mr. John Williams, F.C.S., and explained the principle as follows:—Mercury freezes at 40° C., and boils at +360°, in other words, there is an interval of 400° C. between the melting and boiling of mercury. This space is divided into 1000°: thus 2° C. become 5° Milli., so the proportion between the two scales is very simple. Multiply C. by $2\frac{1}{2}$, and add 100, and you have the *M* number. Proportions of various scales: 5° C. = 9° F. = $12\frac{1}{2}$ M.; 50° M. is not far from 0 F.; 150 M. is about 62° F.; 200 M. rather above blood heat. Certain advantages are at once apparent, the degrees are much smaller than those hitherto in use, thus avoiding the necessity of fractions; again, practically, minus degrees are avoided—for it is very seldom we require to take temperatures under the melting point of mercury, still it is at a glance known what temperatures are under 100; again, as the higher numbers are approached, you know that you are reaching the limit of thermometric registration, and therefore the mind is able to grasp the true comparative temperature better than by other systems.

A discussion followed in which the principal objections raised were, that the zero and 1000° could not be directly estimated, and that owing to the unequal expansion of mercury at various temperatures, to fix two points by the boiling and freezing points of water, and from these mark off higher and lower degrees, would present no difference from the method now used.

The President then read his valedictory address. He commenced by stating that thirteen meetings of the Association had been held during the past session, and then gave a short summary of the papers which had been read. Incidentally, he referred to an opinion he had expressed in his address at the commencement of the session, that pharmacy was a science and an art, to which opinion, he said, objections had been taken. In its support, however, he quoted the following words of Professor Hofmann at a meeting of the Pharmaceutical Society, held in April last. Professor Hofmann had said:—"It would seem that chemistry, which owed its origin to pharmacy, was now, after having almost forgotten this early association, returning in a measure to the source and fountain-head accepting as it did most gratefully the endless variety of subjects which the researches in pharmacy and the natural sciences allied with it were daily presenting for inquiry." He (the President) would therefore maintain that the strides of progressive knowledge had given to pharmacy a place amongst the sciences; and it was an art far more than a mechanic's art if viewed in all its true bearings, although he admitted that conventionally amongst pharmacists and chemists were included those who simply *read* pharmaceutical products and chemicals either in the compounding of medicines or to supply human wants. With respect to the history of the other business of the session, the President continued:—"Your Council decided at the commencement of the present session to vary the provision for our general meetings by making alternate evenings of a more conversational character, and hoped by doing this to induce younger members to come forward to the front ranks. Four such meetings have been held. Two in the Gallery of Art—at which, after the formal business had been transacted, the members were invited to inspect microscopes and objects likely to be of interest to them. There was at first an impression that these meetings were intended for students only, as suggested last session, the attendance, therefore, was very small. Two meetings were held here; at the first, Mr. Abraham read a short paper entitled 'Some Notes on the Starches of Commerce,' and, with illustrations exhibited under his splendid microscopes, showed how easy a matter it is to detect adulterated starches, or to distinguish true wheaten starch, from the flattened oriform shape of its granules. We learned from this paper that a very small proportion of the starch powder of commerce is of the orthodox standard. I have every confidence that these meetings will be much more appreciated if continued another session, as the attendance at the last was much larger, and the expressions of approval by those who were present was encouraging. Our best thanks are due to Messrs. Abraham, Davies, Murphy, Armstrong, and Redford, for exhibiting microscopes and other objects of interest, explaining them to those present, and then contributing to make the intermediate meetings successful. The discussions which have taken place have been quite up to the average of previous sessions; they have been interesting, legitimate, and well maintained with that gentlemanly courtesy with which alone they should be. We have had several contributions of importance to our museum and library, and your thanks have been duly accorded to the donors. Eight members, and 3 associates have joined our Association which at present numbers 131 members, and 19 associates. Though I have so far been able to report favourably of work done, which I hope I may say will bear comparison with any previous session, I regret that my efforts have not been rewarded with the encouragement I could wish—'All that glitters is not gold.' The attendance at our meetings has been small—comparatively very small, and although this is an evil which is shared by most kindred associations, it is a matter of regret to me that the members have not felt the provision which has been made sufficiently attractive for them to attend. I admit that there have been many difficulties in the way; the weather on each of the evenings of our earlier meetings was most inclement; there have been many attractions of a scientific nature provided elsewhere—perhaps during no previous session have there been so many, the Science Lecture Association and the Corporation Free Lectures being more numerous. Again, our members are scattered over a large area, and, perhaps, our meeting room is not sufficiently central. However, I am thankful for great mercies, with only small audiences, and can only all the more appreciate the presence of those who have helped to bring our session to a successful issue. I have another grievance—our School of Pharmacy has simply proved a failure, the classes have not yet terminated, but I am sorry to say that the attendance has been so small that either the Association has filled her mission in providing these classes, or there is room for great alteration. I am inclined to think we make a mistake in having a proviso that a minimum number of students must join before the classes are held—it causes a feeling of uncertainty amongst intending students. Your Council discussed the desirability of withdrawing this proviso by providing fees for the teacher and looking for remuneration from the students. I regret that it did not see its way to obviate the difficulty, at least, not in such a way as our very able teacher, Mr. Davies, could see his way to accept. Mr. Davies, however, voluntarily removed the proviso, and the classes have been held. There are here also difficulties to contend with; many students have a long distance to come, and it is difficult to arrange a suitable hour which shall be convenient to all concerned. I trust your Council will yet see its way to announce that next session the pharmacy classes will be held irrespective of the number of applicants, for I cannot help thinking there should be a want for such a school in this town, and this may now be felt more since it has been ruled that pharmaceutical chemists in business are eligible candidates for the office of public analyst. I trust my successor will be more successful in this matter. Amongst several of our members there is a feeling that our meetings should be more scientific, that there are other scientific chemists in the town who should be induced to join us, and that these members who do not attend should be provided for in this way. I am inclined to sympathize with this, and think that the idea of holding strictly scientific meetings alternately with those which shall be of a conversational nature, with a short paper provided of special interest to pharmacists, would be more advantageous. At the same time we must not overlook the fact that the Association originated with the pharmaceutical element; by it the excellent museum and library have been formed, and with this there is a grand nucleus for further development. One difficulty I am thankful to say has been quite settled during the present session, *i.e.*, the admission of trade questions. A distinct association has been formed with this object, confined to retail traders only; several members have joined, and although they have appointed an official secretary, the urgency of their formation has proved such, that they have not since called a single meeting to accomplish their objects. The President concluded his address by thanking the members of the Association for the kindness and courtesy shown to him during his term of office.

A vote of thanks to the President for his valuable address was proposed by Dr. Nevins, and seconded by Messrs. Redford, and Armstrong. The motion was carried by acclamation, and the meeting closed.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of Executive Committee,

The Committee met at 10 a.m., on the 19th inst., at 17, Bloomsbury Square. Professor Bentley, Vice-President, in the chair.

The minutes of the previous meeting were read and confirmed.

Professor Attfield announced that as a result of the invitations to membership he had issued last summer, not only had five hundred candidates been elected at the Annual Meeting in August, but about four hundred additional names had since been received.

The Committee then duly elected the four hundred candidates.

Mr. Louis Siebold, editor of the 'Year-Book,' attended the Committee and presented a report from which it appeared that he had quite recovered from the illness which had caused delay in the issue of the current year-book, that materials for the next year-book had already been arranged and posted so far as was possible to a recent date, and that the whole of the manuscript of that volume would, he was sure, be laid on the table at the next annual meeting.

In connection with the Bell and Hills library fund, Mr. Hills suggested that if the Bristol Pharmaceutical Association accepted the usual grant of books, they should, if practicable, be obtained, bound, and presented in time for them to be placed on the table at the annual meeting of the Conference.

Mr. Schacht undertook to make inquiries, and, if possible, carry out arrangements by which Mr. Hills' suggestion should be carried into effect.

Ordered, that the salary of Mr. R. H. Davies, the assistant secretary, be increased from £25 to £40, dating from the commencement of the current year.

Professor Attfield reported that since the commencement of the Conference year he had received 2328 subscriptions, of which 1800 had been sent in response to a first application, 392 after applying a second time; 136 members had required three applications, and 422 subscriptions still remained unpaid. The total number of members was about 2750. He had been endeavouring to interest colonial pharmacists in the Conference, and as a result several Australian chemists had joined, many of whom had requested to be supplied with back volumes of the 'Year-Book,' and had offered to contribute any local information required in aid of research. The 'Year-Book,' 1874, had been sent to every member who had paid the subscription.

The date of the approaching annual meeting for 1875 was announced—Tuesday, August 24, and Wednesday, August 25; and the usual meeting of the Executive Committee on the evening of Monday, August 23, at Bristol.

The meeting for 1876 will probably be held in Glasgow; for the British Association for the Advancement of Science will assemble there in that year, and an invitation to the Conference from the Glasgow Chemists and Druggists' Association has already been received.

CHEMICAL SOCIETY.

Thursday, May 20, 1875. Professor Abel, F.R.S., President, in the chair. After the usual business of the Society, Mr. A. H. Smee read some "Notes on Milk in Health and Disease." From the results of numerous experiments, he finds that when cows are fed on sewage grass the milk soon goes putrid, and the butter made from it is soft and yeasty and rapidly becomes rancid. He also noticed the outbreaks of typhoid which had occurred in various places owing to sewage water having been used to cleanse the dairy utensils or to reduce the quality of rich milk to the lowest standard permitted by law. A long and interesting discussion followed, after which Mr. W. H. Deering read a paper "On some Points in the Examination of Waters by the Ammonia Method," in which he proposes certain modifications to facilitate the application of the Nessler test and eliminate incidental errors. There was also a communication from Professor H. Howe, "On some Nova Scotian Triassic Trap Minerals." The meeting was afterwards adjourned until Thursday, June 3, for which the following papers are announced:—"On the Effects of Pressure and Cold upon the Gaseous Products of the Distillation of Carbonaceous Shales," by J. J. Coleman; "On the Agricultural Chemistry of Tea Plantations of India," by Dr. Campbell Brown; "On the Structure and Composition of Pseudomorphic Crystals, having the form of Orthoclase," by J. A. Phillips; "On Nitrosyl Bromide, and on Sulphur Bromide," by M. M. Pattison Muir; "On the Action of Chlorine on Pyrogallol," by Dr. Stenhouse and Mr. Groves; "On some new Derivatives of Alizarin," by W. H. Perkin; "On some Metallic Derivatives of Coumarin," by Robert Williamson; "Note on the Action of Chlorine on Acetamide," by Dr. E. W. Prevost; "On the Action of Dilute Mineral Acids on Bleaching Powder,' by Ferdinand Koffer; "Note on Sulphate of Narceine and other Narceine Derivatives," by Dr. Wright and Mr. Beckett.

PHILADELPHIA COLLEGE OF PHARMACY.

The seventh meeting of this College for the present session was held on April 20th, the President, Mr. Dilwyn Parrish, in the chair.

Amongst the donations to the library and cabinet was a copy of the 'Year-Book of Pharmacy,' and a specimen of a new variety of cinnamon, which is mentioned on page 477 of Flückiger and Hanbury's 'Pharmacographia,' under the name of China cinnamon; it was in unscraped quills, and had a saccharine and pungent cinnamon taste. A sample of the same in powder was likewise exhibited; it was much darker in colour, but of a stronger cinnamon flavour than the ordinary powdered Chinese cinnamon.

The President presented a bottle of "crab orchard salt," and Mr. G. W. Kennedy remarked that in Tennessee this salt, but of a darker colour than the specimen, was sold to be used in place of Epsom salt.

At the request of the President, Mr. R. V. Mattison gave the following information respecting "crab orchard salt:"—

"Crab orchard salt is obtained from a tract of land in Lincoln county, Ky., about three miles wide and fifteen long, called the 'Epsom Belt.' Wells are dug in the ground, and the rain, percolating and lixiviating the soil, which contains a large percentage of the sulphates of sodium, potassium and magnesium, collects in these wells, and is from thence evaporated in iron kettles, and brought into the market in barrels. As found commercially, it consists of varying proportions of organic matter and water, from 15 to 40 per cent., with balance of the above alkaline sulphates and some sodic chloride. The insoluble portion (I have obtained 30 per cent. upon solution and filtration) consists of silicaceous and organic matter, with about one-tenth of one per cent. of ferric oxide.

"A short time ago the product of this belt of land was leased or purchased by a stock company (Col. Shelby, Dr. Blackburn and others), who now control the salt, and have raised the price of it from 23 and 27 cents to 63½ and 75 cents, selling it only in bottles. Regarding Dr. Blackburn's statement that 'a large quantity of artificial salt is sold, and that it is very injurious,' we agree to both statements. First—there is a very large quantity of artificial salt sold. Second—the sale of this artificial salt *is* very injurious, but *only* to the *pecuniary* interests of the company, and not, as Dr. Blackburn, who in the interest of the company desires to impress people with the belief that it is injurious to their health. It is no more so than Epsom salt, or similar purgatives."

Dr. Pile presented a handsome specimen of crystallized bromide of sodium.

Dr. Miller presented three samples of oil of cedar; pure German, cedar of Lebanon for perfumery, and a commercial sample of a strong turpentine in odour; also, Cochin ginger-root and a powder from it; this root is devoid of the coating of lime adhering to bleached Jamaica ginger, but yields a whiter powder; also, a sample of North Carolina and of Texas *serpentaria*. Professor Maisch remarked that the former was the produce of *Aristolochia serpentaria*, Lin., and the latter of *A. reticulata*, Nuttall. The United States' market is now almost exclusively supplied with the latter variety, which is known as Red River snake-root, and is sold for half the price of the former. Dr. Miller also stated that stavesacre was sometimes sold for the seeds of *Delphinium consolida*, Lin.; the latter are much smaller and darker in colour.

Liquor Potassii Citratis.

Mr. Augustus Hohl read a paper in which he referred to the great difficulty experienced in keeping this solution —which in the United States is largely used in medicine —fresh and clear. Many formulæ which he had tried yielded products that always turned turbid and flocculent in a short time. The following, however, he recommended as not open to this objection:—

1. ℞. Citric Acid . ℥i. Distilled Water f℥viii. Dissolve and Filter.	2. ℞. Bicarbonate of Potassium . ʒxi. Distilled Water f℥viii. Dissolve and Filter.

Two solutions are thus obtained ready for use; and when liq. potass. citr. is ordered, all that is necessary is to mix equal parts of the two, allow it to effervesce, and the preparation, fresh and clear as crystal, is ready for use.

The above quantities are double those of the 'United States' Pharmacopœia.'

Wine of Tar.

Mr. J. B. Moore read a paper in which he recommended the following formula for this preparation:—

℞.—Tar, pure	℥xvi., troy.
Glycerin	
Sherry Wine	
Honey	āā f℥viii.
Acetic Acid	f℥i.
Boiling Water	O vi.

Mix the glycerin, sherry wine, honey, acetic acid and boiling water together, in a stone jug or other suitable vessel of the capacity of a gallon. To the mixture add the tar, and shake the whole vigorously for several minutes. The vessel is then to be tightly stopped and placed upon a stove or in a water-bath, resting upon folds of paper, and the mixture digested, for an hour or two, at a temperature of from 150° to 160°. During the digestion, the mixture should be frequently well shaken. When the digestion is completed, the mixture is to be set aside to macerate, in a warm place, for a few days, it being well shaken occasionally during the process. Lastly, strain through muslin, and filter the strained liquid through paper.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture V.

(*Concluded from page 898.*)

Alum is a powerful astringent, producing constipation, and sustaining a persistent dyspepsia so long as it is being swallowed. Nitric acid is an astringent, exerting also a physiological action on the liver. Sulphuric acid is an astringent; and butyric acid, as I found in an original research which I once conducted with it, causes a congested or inflammatory condition of the whole track of the mucous membrane.

Thus each one of these agents added to the alcoholic drinks increases the evils that are likely to arise from the alcohol itself. Let us admit that the added evils are small, nay, I had nearly said, infinitesimal, when considered by the measurement of one administration. But who can measure by that standard? When once the taste for one of these unnatural substances is acquired it grows by what it feeds on, and that which was infinitesimal at the beginning becomes after long continuence a serious charge for the body to bear daily.

The spirit in common use that is most subjected to the chemicals I have named is gin. Gin has to be made cordial, to be sweetened, to be rendered creamy and smooth, to be flavoured, to be made biting to the palate, to be beaded, and what not else. To be made "cordial" it must be charged with oil of juniper, with essence of angelica, with oil of bitter almonds, with oil of coriander, and with oil of carraway. To sweeten it, it must be treated with oil of vitrol, oil of almonds, oil of juniper, spirits of wine and loaf sugar; to "force down" the same it must be further treated with a solution of alum and carbonate of potassa. To be rendered creamy and smooth, it must be sweetened with sugar, and lightly charged with a small quantity of garlic, Canadian balsam, or Strassburg turpentine. To give it piquancy, it must have digested in it shreds of horse-radish. To be made biting to the palate, it must receive that touch of caustic potash of which I have spoken.

As you see the habituated gin-drinker partaking of his favourite drink you observe, often, that he enjoys it the more if it be what he calls "pearly," or "beaded." He holds up the precious liquid in his glass, and as he sees the oily fluid as beads roll down the side, leaving each a creamy train behind it, he rejoices in his treasure. It is *crême de la crême* of gin. Those wicked pearly drops are, to his flushed eyes, the proofs of the purity and excellence of what he would probably tell you was, without mistake, the genuine article. The genuineness consists

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts*.

in the fact that our enthusiastic friend's gin has been beaded by the addition of the following artistic mixture :—An ounce of oil of sweet almonds has been added to an ounce of oil of vitrol. These have been rubbed together in a mortar with two ounces of loaf sugar until a paste has been formed. The paste has next been dissolved in spirit of wine until a thin liquid has been produced ; and this, added to one hundred gallons of gin, has given the fine pearly bead that is so much admired.

Redding, in his history and description of modern wines, narrated in his day the many receipts that were openly published in the then existing publicans' guides and licensed victuallers' directories for the artificial manufacturing of wines, and for modifying spirituous liquors. I have gone for my information to a similar work of the present day, 'The New Mixing and Reducing Book,' which is, I understand, one of the handbooks of the retailer, the same to him as the pharmacopœia is to the druggist, and to be followed in all the varied arts as implicitly. I cannot leave this book without reading from it a quotation that bears directly on the health of the poorer classes, who indulge in gin.

"Gin, it may be observed, is of all the spirits ordinarily kept by a publican the one which, when cleverly managed, yields him the greatest and securest profit. The reason of this is that there is hardly any definite selling strength for gin, especially if it be sweetened. Within very wide limits no complaint is made by customers on the score of weakness, provided only the gin is creamy, palatable, and sharp tasted. But the slightest taint, or the slightest fault of colour, or a sensible difference in the usual flavour, will lead to dissatisfaction and loss of custom. Strong or unsweetened gin is in comparatively little request, and then with few exceptions only amongst the respectable or monied classes. At least three-fourths of the spirit sold over the counter of a public-house consists of sweetened or made-up gin ; and as the sugar greatly alters the character of the liquor and deadens the original strength, it is possible for the retailer to consult his own interests by a liberal addition of water without in any degree exciting the disapprobation, or injuring the health of those who patronize his establishment.

"As a tolerably safe general rule there will be no occasion to fear dissatisfaction when sweetened gin is not brought below 35 or even 40 per cent. U.P. It is then nearly five times as strong as old ale. Much more is thought of a pleasant warming aromatic taste or smack than of simple alcoholic strength. But as the most careful man may sometimes overshoot the mark in reducing, it is advisable to know how to restore the requisite degree of pungency and sharpness, without having recourse to the use of so expensive an agent as spirits of wine. Supposing, then, that by accident the strength of a parcel of gin has been lowered rather too far, a good and cheap remedy is the following :—For 100 gallons, 1 ounce of cassia, ½ ounce of chilies. Steep for a week in a pint of spirits of wine ; then mix well with the gin."

The other spirituous liquors, rum, whisky, and brandy, are less falsified than gin. Rum is occasionally adulterated with an essential oil like butyrin and with butyric acid, these two substances being present in some natural rum, giving to it a special flavour and taste. Whisky is modified by blending, so as to communicate qualities of smoothness and softness. The yellowish colour given to whisky is produced by pouring the spirit into sherry casks, or by stirring it up with the lees of wine. These refined whiskies are prepared for the rich and sumptuous ; for the poor it is recommended that they should be treated with the spirit they understand best ; a sharp and potent drink, that brings the tears into the eyes, and makes the throat smart as it goes down.

Brandy, except when treated with fusel oil, is not, I believe, adulterated with any injurious compound. But it carries with it naturally a peculiar ether, which gives to it a special odour. This ether, a specimen of which is on the table, is very heavy when compared with ethylic ether. Its specific gravity is 862, taking water at 1,000, and its boiling point is 479° on Fahrenheit's scale. It is all but insoluble in water, to which, however, it communicates its peculiar odour. It exerts on the body an injurious influence; it causes nausea, thirst, and pain in the stomach. It seems also to arrest the due secretion of bile.

Secondary Physiological Action of Simple Alcohol.

I leave now the consideration of the evils arising from the action of the different extraneous substances that are present in alcoholic drinks to resume the study of the action of ethylic alcohol itself when it is free of any such combinations. I have to consider under this head the effect of the consumption of alcohol in its slow and progressive course, in what may be called its secondary manifestations of effect upon those who for long periods of their lives submit themselves to its influence.

I have shown that in the course of acute intoxication from this spirit there are four degrees or stages, each degree marked by different series of phenomena. In the secondary, or, technically speaking, chronic intoxication, from the same agent, there are in like manner four distinct degrees, each presenting distinct phenomena. A minority of persons who habitually take alcohol escape with impunity from injury. Some of these escape because they only subject themselves to it on a scale so moderate they can scarcely be said to be under its spell. If they take it regularly they never exceed an ounce to an ounce and a half of the pure spirit in the day ; and if they indulge in a little more than this, it is only at recreative seasons, after which they atone for what they have done by a temporary total abstinence. Others take more freely than the above, but escape because they are physiologically constituted in such manner that they can rapidly eliminate the fluid from their bodies. These, if they are moderately prudent, may even go so far as to indulge in alcohol and yet suffer no material harm. But they are a limited few who are thus privileged, if the term may be applied to them. The large majority of those who drink alcohol in any of its disguises are injured by it. As a cause of disease it gives origin to great populations of afflicted persons, many of whom suffer even to death without suspecting of what they suffer and unsuspected. Some of these live just short of the first stage of natural old age ; others to ripe middle age ; others only to ripe adolescence.

Deterioration of the Body under the First Degree.

The first degree of the secondary action of alcohol is evidenced in those who by constant habit imbibe an alcoholic stimulant to the simple extent of producing arterial relaxation, and of setting the heart at liberty to perform an increased series of motive contractions. They do not, as a rule, receive what is commonly called an excess of any alcoholic drink, but they become trained to a sensation of want for it, to an appetite which, while all seems to go well, they have no desire to resist, though they may keep it within what they conceive are its due limits. Such persons confine their libations to four or six ounces of alcohol per day, a couple of glasses of sherry or of ale at luncheon, three or four glasses of wine at dinner, one or two at dessert, and a mixture of spirit and water before going to bed ; such is a common and a "temperate day," but reckoned up it means at least from four to six ounces of alcohol. The primary effect of such a quantity we know. Continued daily it induces a new physiological and altogether unnatural condition, in which the sense of acquired necessity enforces desire, until at last the spirit is made to become a positive requirement of the organic and the mental life. Every extra effort must be preceded by the resort to the stimulant. Every prolonged weariness must be relieved by the same measure; but when the effect of the measure has speedily subsided, there is left a greater exhaustion than before. Another resource to the artifical aid completes the exhaustion, and makes it pass into dullness and drowsiness without natural and sound sleep, and with an unbearable sense of after prostration.

For many years, in the young and adolescent, this alcoholic life may be carried on without any evidence being rendered of the progress of physical deterioration. In the young the processes of assimilation, of secretion and of excretion, are in their full activity, and the poisonous agent with which the blood and tissues is saturated is disposed of so readily and promptly, it does not stay long enough in contact with these parts to vitiate them. This is a very homely way of putting the fact, but it is scientifically true. The young, therefore, seem to escape, and I believe that up to the close of the first term of the natural life, that is to say, to the close of that period of full growth and developement which extends to thirty years, they sometimes escape so successfully that if they could but stop in their course at that point they might go through the remaining terms of existence without any important modification of function.

Unfortunately it is the rarest of events that a person artificially stimulated by alcohol to the period named gives up the practice. The majority are utterly ignorant of the dangers that are ahead, and the sense of support to which they have been educated by the practice leads them on to pursue it with even a greater reliance upon it than before, and with a feeling of more urgent demand. In a word, the sensation that they cannot do without it, the sensation of lowness and depression when it is by any accident withheld, and the contrast of lightness and activity when it is regained, are so powerful, in their influences upon the mind, there is no resisting the belief of the absolute necessity.

But when the body is fully developed; when the extra vital capacity which attended youth is expended in growth and development; when all the organs have assumed their full size and activity; when the balance of secretion is so nicely set in all parts that not one secretion can be disturbed without a disturbance of the whole; when the spring of the elastic tissues is reduced; when the lungs cannot fail ever so little in their function of throwing off the gaseous products of combustion without a vicarious extrusion of gases into the alimentary canal; when the completed organic moving parts become encumbered with fatty matter interposed between them, or laid out around them; then the effect of alcoholic spirit begins to be realized. The fluid is now retained longer in the living house; is decomposed less quickly; is thrown out by primary or secondary elimination less speedily.

The action of alcohol under these new conditions, so favourable in every sense to the series of changes it is capable of effecting, is twofold. The action in the first place is purely mechanical. We are aware that it leads to temporary paralysis of the vessels of the minute circulation, and that upon this the heart responds with a quicker propelling stroke. Thus the vessels throughout the whole of the body are dilated, and are held in a state of unnatural relaxation and unnatural tension. Under this persistent pressure their diameters change in course of time, and the whole of the marvellous webwork of blood, upon which the organs of the body are constructed, is deranged, in its mechanical distribution, over its extended surface. During this time, too, the function of the heart becomes perverted. The heart is truly an automatic organ, but it is still an organ which feels none the less severely the effect of stimulus. If it make to-day an unnatural number of one hundred and twenty-five thousand strokes, it cannot to-morrow sink back, from absence of its stimulus, to the normal one hundred thousand without evidencing some disturbance of action, some feebleness, some hesitation, or some palpitation. In fact, as it is an organ which by its own stroke feeds its own structure with blood, it is the first to suffer from irregular supplies of blood. Thus under alcohol the nutrition of the heart is mechanically modified. Whipped into undue work, it becomes, like the muscles of the blacksmith's arm or the opera dancer's leg, of undue size and power; and in proportion as this evil increases the necessity for the stimulus it calls for grows more urgent.

In turn this extreme power and force of the heart tell upon the vessels that are fed by its impulsive stroke, and so all the organs that are constructed upon those vessels appreciate with abnormal sensitiveness the whip of the stimulus, and the languor when the whip is withheld.

Of itself this extreme sensitiveness of the heart is sufficiently momentous, but the ultimate results upon the body at large are perhaps more important than the pure local change that is instituted in that perfect and elaborate pulsating mechanism. The heart not only becomes enlarged, but its various valvular and other mechanical parts subjected to undue strain are thrown out of proportion. The orifices in it, through which the great floods of blood issue in their courses, are dilated. The exquisite valves become stretched, and prevented from assuming their refined adaptations. The minute filamentous cords which hold the valves in due position and tension are elongated, and the walls of the ventricles or forcing chambers are thickened, or as we say, technically, are hypertrophied. Throughout the whole of its structures the central throbbing organ is modified both in its mechanism and in its action.

But such central modification cannot possibly go on long without the institution of other changes at the opposite extremity or circumference of the circuit of the blood. At one moment the vital organs feel the pressure of the too powerful stroke of blood; at another moment they are suddenly aware of an enfeebled stroke. The brain is, for the instant, conscious of a flicker of power; it is like the faintest flicker of gas, which is observed when, by an accident, the pressure is disturbed at the main, but it is there, and the person who experiences it is cognizant of its central origin. So matters progress often for months, or for years, without further evidence of subjective or objective sign of increasing evil. The worst evidence that exists is, probably, the necessity for a more frequent repetition of the stimulus under additional stress of work or excitement.

While these changes in the simple mechanism of the circulation are in course of advancement, there are also in development certain other changes which are much more delicate and minute, yet not less important. These consist of direct deteriorations of structure of the organic tissues themselves. We are, at the present time, only on the borderland of a new knowledge on this subject, and I myself am, in this matter, a mere outpost wandering wonderingly, and trying to observe what is going on, but as yet, though thus advanced, unprepared to speak with so much precision and fulness of detail as I would desire. The following, however, simply spoken, seems near the truth in respect to the degenerative changes of organic structure from the continued use of alcohol. Alcohol produces physical deterioration by destroying the integrity of the colloidal matter of which the tissues are composed. I have explained that all the organic parts are constructed out of colloidal substance; that every part, including the blood vessels, to their minutest ramifications, are composed of this colloid material arranged in different forms and plans to suit the design of the part, whether it be a tube, like an artery, a bundle of cross-cut fibres like a muscle, or a refracting globe like the crystalline lens of the eyeball. That these parts should be kept in their integrity, in the midst of their diversity, the ultimate structure of which they are composed must be held in proper measure of construction with water. Disturb the relationship that should exist between the colloid and its combining water, and the character of the colloid is at once changed. Here, for example, is a colloidal fluid, called albumen. I pour a little of it on to a glass plate as a thin watery film. I spread over it a little finely powdered caustic soda, by which I remove and fix some of the water which previously held it as a liquid. Now observe what has occurred. The thin liquid is transformed into a transparent membrane which possesses elasticity. Again, into this little porcelain cup I pour a small quantity of the same solution, and then I drop into the solution a bead of soda and soon I can lift the solution from the cup in a solid mass, shaped like a concavo-convex transparent lens. I could multiply these facts indefinitely, but I am anxious to indicate only one particular fact, viz., that alcohol and its derivative aldehyd possess also by their affinity for water, the property of destroying the integrity of the colloidal form of matter. Thus they solidify, or render pectous the colloidal structures. Here is a solution of albumen. I add to it alcohol. The albumen is rendered thick or pectous. Here is a solution of casein; I add to it aldehyd; the casein is rendered thick or pectous.

Animal tissues subjected to alcohol can be perverted to any degree, and in the most diverse and apparently contradictory ways. I can hold blood permanently fluid with alcohol; I can solidify it with the same agent. I can reduce the size and modify the shape of the blood corpuscles, and I can so modify those fine and delicate animal membranes which dialyse or allow to pass through them the saline matter of the blood and secretions, that the process of dialysis shall be impeded, and that which should pass through shall be left in combination with the membrane. I can destroy the elasticity of the blood vessels in the same way, for that depends upon the presence in them of a gelatinous colloid substance called elasticin.

When, therefore, alcohol holds long-continued contact with the perfectly developed colloidal tissues, its action upon them to produce physical deterioration is simply inevitable, and from this cause arise those fatal lesions of local organs which mark the different phases and stages of alcoholic disease. The commencement of the change sometimes shows itself visibly on the surface of the body. The vessels of the face become permanently enlarged and suffused with blood. In cold weather, the blood circulating imperfectly through these vessels, and, not fully aërated, gives to the skin that dull leaden hue which is so characteristically significant of prolonged indulgence; in hot weather, the blood circulating more freely and purely, gives to the skin a red hue, and often a deep red blotch, which is hardly less demonstrative.

In this stage of alcoholic disease eruptions upon the skin occur to declare the injurious action of the spirit upon the colloidal gelatinous textures. The epidermis or scarf skin is imperfectly thrown off; it dies upon the surface, but owing to deficient vascular and nervous tone beneath, it is not replaced so quickly as is natural. Thus the dead *débris*, in form of scale and sometimes with fluid beneath, accumulates; the superficial nervous surface, which should be protected by the newly formed epidermis, is exposed, and irritation and pain follow as a consequence.

These evils. in these the slighter stages of alcoholic disease, are often connected with others, which are perhaps passing, but which give rise to very unpleasant phenomena. There is what is called dyspepsia or indigestion, to relieve which the sufferer too frequently resorts to the actual cause of it as the cure for it. There is thirst, there is uneasiness of the stomach, flatulency, and a set of so-called nervous phenomena, which keep the mind irritable, and make trifling cares and anxieties assume an exaggerated and unnatural character. From the earliest period in the history of the drinking of alcohol these phenomena have been observed. "Who," says Solomon, referring to this action, "Who hath woe? Who hath contentions? Who hath babbling? Who hath wounds without cause? Who hath redness of the eyes?"

What modern physiologist could define better the steady and progressive effect of alcohol upon those who even under the guise of temperate men trust to it as a support? And yet these evils are minor, compared with certain others I have to bring before you in my next and concluding lecture.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Sale of Food and Drugs Bill.

On the consideration of this Bill in the House of Commons on Friday, May 21, several verbal amendments were introduced, and an amendment by Mr. Sandford, providing that the retail dealer shall have right of action against the wholesale dealer, was also agreed to.

An amendment was afterwards inserted on the motion of Mr. Sclater-Booth, adding to the 9th clause a provision "that no person shall hereafter be appointed an analyst for any place, under this section, who shall be engaged directly or indirectly in any trade or business connected with the sale of food or drugs in such place."

In clause 13, Dr. Cameron moved an amendment providing that samples of articles alleged to be adulterated should be marked and sealed by the analyst. On a division the amendment was rejected.

Some verbal amendments were agreed to.

On Monday, the 24th inst., the Bill was read a third time.

Prosecution under the Adulteration Act.

Adulteration of Milk.

At the Swansea Court, on the 6th inst, William James, milk contractor to the Swansea Union Workhouse, was convicted of adulterating the milk supplied by him. At a former hearing the defendant appears to have stated that a sample of the same milk had been analysed and reported by Mr. Stoddart to be pure. The case was therefore adjourned that a portion of the sample produced by the prosecution might be analysed by him. Mr. Stoddart now reported that in this sample there was a deficiency of 15 per cent. of solids, which agreed with the report of the town analyst. The Stipendiary, after expressing an opinion that the sample forwarded by the defendant was not of the same quality as alleged by him, strongly censured his conduct and inflicted a fine of £10 and costs, amounting altogether to £15 13*s*. 6*d*.

Prosecution of an Oilman for the Sale of Poison.

Mr. W. V. Aldridge, oil and colourman, of Islington Green, having been summoned by the Pharmaceutical Society of Great Britain for the penalty of £5, incurred by him under the provisions of the Pharmacy Act for selling by retail oxalic acid, he not being a registered person, has paid the penalty and costs into court.

Supposed Poisoning by Arsenic.

On Monday, the 24th inst., an inquest was held at Fishtoft, near Boston, Norfolk, on the body of Thomas Green, who died on the 17th inst. from the effects of arsenic taken in tea on the morning of Thursday, the 15th. The deceased immediately after partaking of the meal was seized with intense pain. He was promptly attended by Dr. Tuxford, who was satisfied that the symptoms were those of poisoning by arsenic. The wife of the deceased and his son were also taken ill, but recovered. A *post-mortem* examination was made of the body of the deceased, in which all the symptoms of irritant poisoning were present. At the adjourned inquest Dr. Lowe, county analyst, deposed that the deceased died from the effects of arsenic. The evidence adduced failed to show that the deceased had lived on bad terms with any one; and, although the coroner considered that arsenic could not have come by accident into the tea, the jury returned a verdict to the effect that there was no evidence to show who had administered the poison which caused death.—*Times*.

Reviews.

TYPHOID FEVER; ITS CAUSE AND PREVENTION. Illustrated by the Recent Epidemics in Crosshill and Eaglesham. By EBEN. DUNCAN, M.D., Fellow of the Faculty of Physicians and Surgeons, Glasgow; Surgeon to the Deaf and Dumb Institution. Glasgow: James Maclehose. 1875.

The subject of the propagation of typhoid fever by means of infected milk has, of late, attracted considerable attention; and although the profession has had ample opportunities of examining the merits of the evidence adduced in support of the theory, the public at large has been debarred from forming any definite opinion, owing to the technical character of the discussion. It will be readily admitted that the co-operation of the public is essential towards the lessening of preventible disease, and this co-operation can be obtained only by educating it as to the causes which produce, and the means which may be taken to prevent the spread of contagious diseases.

It is with this object that Dr. Duncan has related in plain, intelligible language the history of the origin, progress, and termination of a recent epidemic of typhoid which he has traced to a poisoned milk supply; and he has "endeavoured, as much as possible, to avoid technicalities, so that the public may judge as to how conclusions on such a subject are arrived at."

We congratulate Dr. Duncan on the manner in which he has performed his task, and we are of opinion that the general reader has much reason to be thankful to him for such a lucid exposition of a difficult and involved problem.

LECTURES ON SKIN DISEASES, delivered at St. Vincent's Hospital, by E. D. MAPOTHER, M.D., Professor Royal College of Surgeons, late Examiner in Surgery, Queen's University, Dublin. With Illustrations. Second Edition. Dublin: Fannin and Co. 1875.

Notwithstanding the existence of a host of works on skin diseases, this little volume asserts its right to appear in a second edition, and we hope it will find a ready welcome among students and young practitioners in England. It is far from being a complete and systematic skin manual, nor does it claim to be "a special treatise on skin diseases," but contains a simple description of certain diseases which are of common occurrence and of easy diagnosis, together with a short but interesting account of cerebro-spinal meningitis, the syphilitic and scrofulous diathesis, and an appendix on baths, watering places, disinfection, etc.

Obituary.

Notice has been received of the death of the following:—

On the 14th May, 1875, Mr. Thomas Barford Castell, Chemist and Druggist, of Plaistow, Essex, aged 46.

On the 17th May, 1875, Mr. Joseph Pitts, Chemist and Druggist, of Windhill, Yorkshire, aged 62.

On the 19th May, 1875, Mr. William Thomas Taylor, Chemist and Druggist, of Bristol, aged 42.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE DECREASE IN THE NUMBER OF PHARMACEUTICAL CHEMISTS.

Sir,—In the report of the Council presented at the annual general meeting of the Society is a paragraph calling attention to the fact of a decrease to the extent of sixteen in the numbers of the "pharmaceutical chemist members," and all those connected with our Society must unite with the Council in lamenting "that so many stop short at the grade of associates." At the same time it appears to me that the reason of this falling off in numbers is traceable to the very small advantages enjoyed by the Major men over those who have only passed the Minor Examination, and it is certainly very difficult to make out a good case when recommending young men to "continue in their onward course until they have attained the highest rank," if they request you to state the benefits they may expect to derive from so doing. It is, of course, very easy to remind them of the honour they will obtain from affixing the mystic letters P. C. to their names, but they will probably reply that "le jeu ne vaut pas la chandelle," and it is certainly extremely doubtful whether anything like a thousand persons outside the Society can appreciate the differences between pharmaceutical chemists and members and associates of the Pharmaceutical Society.

The admission of chemists and druggists in business prior to 1868 as members was only just and natural, but that associates who have become such by examination since that date should be granted all the privileges of pharmaceutical chemist members as soon as they go into business on their own account seems hardly fair towards those who have expended the additional time and money requisite for passing the Major. Whilst fully aware that many chemists and druggists are quite equal and even superior to some pharmaceutical chemists as trades- or professional men, I consider that the Pharmaceutical Society would advance both its own interests and also those of pharmacy in general by granting higher privileges to the latter than are enjoyed by the former class.

Should the project of extending the exemption from serving on juries be carried out, there will cease to be any practical benefit derivable from the Major qualification, and it is after all useless for the Council to expect any increase in the numbers of "pharmaceutical chemist members," unless there is some more than titular advantage attaching to the rank of pharmaceutical chemist.

URTICA.

May 25, 1875.

DISPENSING CHARGES.

Sir,—I am not one to trouble myself about the peculiarities of my neighbours, but a case came under my notice to-day which may not be uninteresting to some of your readers.

A prescription, written by a physician of standing, was presented to me to be dispensed. The following is a copy:—

℞ Potassii Bromid. . . . . ℥j.
Ammon. Bromid. . . . . ʒiiss.
Sp. Ammon. Aromat. . . . . . . ʒij.
Aquæ ad . . . . ℥xvj.
℥ss. ter die.

I may say that my prices are a little under those of the leading London firms, to whom in every other respect I endeavour to be equal.

As I am noted for being a high charger, my patron came quite prepared to pay me half-a-crown, but fancy his astonishment when I said four shillings. I was offered three shillings, or the prescription would be taken to where it had been dispensed before; contrary to my usual custom I offered to take three and sixpence, or decline having anything to do with it, and after much altercation I was allowed to dispense it at that price.

It seems that the physician recommends his patients to to take their prescriptions to a certain chemist who charges half the usual price for the medicine; the advice was acted upon in this instance, and what do you think, sir, was the charge? One shilling!

The same gentleman, in illustration of the difference in chemists' charges, mentioned a case in which a neighbour of mine, not noted for being a high charger, had charged eighteen pence for what a leading chemist (an occasional correspondent of yours) in the same town had charged sixpence. Possibly the latter gentleman had the alternative of taking that price or seeing the prescription taken to the establishment of his "cutting" neighbour. I have no comment to make, but I wonder if this is the system by which we are to make ten thousand pounds in twenty-five years.

A North Countryman.

SAXIFRAGA TRIDACTYLES ONE OF THE CARNIVORA.

I trust "Botanist" will pardon me if I, an outsider in the discussion between himself and Mr. G. C. Druce on the carnivorous propensities of *Saxifraga tridactyles*, venture to suggest that he is rather hasty in drawing his conclusions. First he asks, is the plant known to the latter gentleman? and insinuates that it can scarcely be one of the raptores on account of its diminutive size. May I ask "Botanist," does he know any of the Droseraceæ, either Rotundifolia or Longifolia? That *Drosera rotundifolia*, in common with other raptores (whatever "Botanist's" opinion may be), derives some nourishment from the decomposition of dead insects admits of little doubt, and yet it is a diminutive plant, its rosette of leaves rarely exceeding 2½ inches in diameter. With regard to the probable strangulation of a bluebottle fly, I do not think it likely any more than "Botanist." But are bluebottles the only insects in creation? I have seen insects, whose muscular power was very many times greater in proportion to their size than man, completely overpowered after a hard struggle with the hairs of the spoon-shaped leaf of *Drosera rotundifolia*; and from the first moment of contact they exhibited every appearance of terror. I think this argues that the fluid secreted by these leaves contains some other power than that of simple adhesiveness, and that a proportionately large insect may thus be overcome. Indeed, I have seen insects completely asphyxiated, if not quite dead long before the leaf had curled up sufficiently to exert any pressure on the body. He also asks some "advanced believer" to oblige him with the alimentary canal or digestive organs of one of these plants for examination. He seems to imagine that these two are absolutely necessary for the assimilation of food, but if he examines some of the lowest forms of animal life he will find that they are not indispensable. Take, for instance, the Amœba or Proteus animalcule. There is no permanent mouth, no stomach or alimentary canal of any kind, no respiratory or excretory organs, and even no distinct aperture for the extrusion of indigestible food. It has no nervous system or organ of sight or hearing, only having a slight susceptibility to light, not more marked than in most of the free moving Diatoms, and its method of feeding is likened to sinking a stone in a lump of dough. I think that Drosera, whether plant or animal, is a more highly organized being than the Amœboid animalcule. And as for the last observation in "Botanist's" letter, I may ask him if he perceives any immediate increase in the stature of a growing boy after his dinner. I have heard of people seeing the grass grow, but always thought it a figure of speech. I suppose I was mistaken.

A. H. Baldwin.

Clifton, May 15, 1875.

W. F. C.—(1) "The widow of a chemist and druggist lately deceased" could only legally carry on the business of her late husband if she be, and so long as she may remain an "executor, administrator, or trustee of the estate," and the business be conducted by a person registered under the Pharmacy Act, 1868. (2) The provisions of the Pharmacy Act apply only to the "poisons" enumerated in the Schedule A, and such as may be added thereto by the Council of the Pharmaceutical Society.

Lickiss.—(1) Copies of Dr. Richardson's lectures on Alcohol may be had on application at the house of the Society of Arts, John Street, Adelphi, price 2s. (2) Yes. (3) The Cantor lectures are delivered before the Society of Arts, and were endowed by the late Dr. Cantor.

X. L.—Yes, provided that the preparations mentioned contain no poisons included in the poison schedule under the provisions of the Pharmacy Act.

G. Watt.—*Stellaria Holostea.*

H. J. Blathwayt.—(1) Scrophulariaceæ. (2) Rosaceæ. (3) Compositæ. (4) Yes. The answers might have been obtained readily by referring to the index to Babington or any similar book.

J. M. Fairlie.—As the report of the meeting referred to was an official one, furnished by the Honorary Secretary of the North British Branch, we think it is proper that any proposal to supplement or correct it should be submitted to that official before being published in the Journal.

Reade Bros.—We do not think that the word "unknown" is introduced into the Pharmacy Act in any incomplete or dubious sense. We are of opinion that, as in the Arsenic Act, the word is meant to imply such knowledge as would enable the vendor to speak regarding the purchaser's name and identity, so that, in case of accident, he should be able to furnish the name and whereabouts of the purchaser to the authorities, and depose to his identity on his being brought before a tribunal.

T. Field.—The omission referred to is in accordance with the decision officially announced more than twelve months previously and continually since then, viz., that "after the 31st day of December, 1874, the medical Latin will be discontinued" in the Preliminary examination. We do not think, however, that your previous ignorance of this fact should prove to be to your disadvantage.

"*Cymru.*"—(1) Yes, an apprentice may obtain books from the Library, in accordance with the regulations, a copy of which may be obtained on application to the Librarian. (2) The success of such an association would depend mainly upon the assistants and apprentices themselves. (3) Apply to the publisher. (4) No, if the article is worth reading as you intimate, it will not be thought too much trouble to turn to the last volume for it. (5) No. (6) Not necessarily.

G. C.—The question is one that should be submitted to a professional analyst.

"*Registered Apprentice.*"—We do not know; apply to the publisher of the book, Mr. Van Voorst, Paternoster Row.

J. W. Lloyd.—We are indebted to you for your enclosure, and shall be glad to receive at any time any intelligence that you may think would be of interest to our readers.

S. Newbury.—See a "Chapter on the Microscope," by Mr. Pocklington, in vol. ii. of the present series of this Journal, pp. 441 and 482.

"*Alresford, Hants.*"—The label forwarded would necessitate the use of a stamp.

T. H. W.—The Act 29 and 30 Vict. c. 64, s. 8, provides, that "no person shall use methylated spirit, or any derivative thereof, in the manufacture, composition, or preparation of any article whatsoever, *capable of being used* wholly or partially as a beverage, or *internally as a medicine.*" Sulphuric ether and chloroform are specially exempted from this provision.

"*Douglas*" and "*Oxygen*" are referred to the rule respecting anonymous communications.

G. P.—By rectification.

ERRATUM.—The following is the exact form of the resolution proposed by Mr. Urwick at the Annual General Meeting:—

"Resolved,—That the report of the Council now read be received and adopted, and printed in the Journal and Transactions of the Society."

NOTICE.—Considerable inconvenience and disappointment are frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ*. A compliance with the explicit instructions published weekly over our Editorial columns will prevent delay, and the consequent annoyance.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Cleaver, Mr. G. W. Fowler, M. R., V. V. V., W. T. S., S. C., "An Apprentice," "Ilex."

We are compelled to defer answers to several communications.

EXPERIMENTS UPON THE ALKALOID OF JABORANDI—CRYSTALLIZATION OF ITS SALTS.

BY A. W. GERRARD,

Teacher of Pharmacy, etc., University College Hospital

In a communication to the *Pharmaceutical Journal* of May 1st I described a process for the preparation of the alkaloid of jaborandi. I also stated that, judging from its characteristics, it appeared to me somewhat doubtful whether it would yield itself in a crystalline condition. Subsequent results have, however, I am pleased to say, dispelled my doubts. A quantity of the alkaloid weighing forty-five grains was prepared. To this distilled water was added and dilute sulphuric acid drop by drop until the alkaloid was nearly dissolved and the solution was neutral. The solution was set aside to evaporate slowly. At the end of three days it had become of a syrupy consistence with no appearance of crystallization; in three days more the portions adhering to the side of the capsule presented a granular appearance; a portion placed upon a glass slide and examined under the microscope showed with a high power a few prismatic crystals. After four days' further waiting it failed to yield itself as a definite crystalline substance. I now prepared a fresh portion of the alkaloid, which I divided into two parts; one was neutralized with hydrochloric acid, the other with nitric acid, and set aside. In twenty-four hours they were examined; the nitric acid solution had yielded a mass of fairly well-defined colourless crystals, with a substratum of light brown coloured matter; the hydrochloric solution presented no crystals. At my earliest opportunity I submitted the crystals of nitrate to Dr. Sidney Ringer, who was glad to receive them for the purpose of applying the therapeutic test which should be final as to their identity with the active principle and alkaloid. I append the report of Mr. L. S. Jameson, Dr. Ringer's assistant.

"At 1·45 P.M., gr. ss. of crystals of nitrate of pilocarpine was given to patient; his temperature 99·4, and pulse 104, dinner having been taken one hour and a half previously. No visible effect till 2·30 P.M., when face and chest became more flushed, and a slight perspiration broke out over the same parts. In about five minutes the whole body was covered with a profuse perspiration, the patient at the same time spitting a large quantity of saliva; temperature 98·8, pulse, 100, and no effect upon the eyesight. The salivation and sweating continued till 7·20 P.M., both much diminishing during the last three quarters of an hour. After this patient got up and dressed himself, feeling very thirsty, otherwise perfectly well.

"No difference in sphygmographic tracing taken before and during sweating."

Following is a report of its action upon the eye:—

"At 11 A.M. a drop of solution of nitrate of pilocarpine, gr. i. to ℥i., put into each eye; in about twenty minutes pupils were contracted to about the size of an ordinary pin's head. No pain or uncomfortable sensation produced.

"Before administration patient could not read more than a word here and there of 4½ Snellen's Test Types, when held at the end of the bed, a distance of five feet.

"When pupils contracted to above size she could read the whole paragraph continuously and with ease four feet beyond the end of the bed.

"Same results obtained in another case when the same solution was used, but distances at which patient could see were not measured."

Professor Attfield has kindly undertaken to make a combustion, etc., of this substance as soon as I am prepared to submit to him a sufficient portion in a purified condition; meanwhile, I trust to be enabled to continue my experiments upon this interesting alkaloid, which promises to be an important addition to materia medica.

Since writing the above the hydrochlorate has completely crystallized.

THE CHEMICAL EXAMINATION OF CARNAUBA ROOT.

BY EDWARD LAWRANCE CLEAVER, F.C.S.

A small quantity of Carnauba root having been placed at my disposal a short time since, through the kindness of Messrs. Symes and Co., of Liverpool, I proceeded to examine it in order to ascertain whether or not it contained any easily isolated active ingredient.

The sample sent to me was in pieces from 12 to 18 inches long, of about the thickness of the little finger, consisting essentially of two parts, the external or cortical part, being very friable, easily separated and powdered, and having a mawkish slightly bitter taste; the internal being hard and tough, extremely difficult to powder, and totally devoid of bitterness or other flavour.

A portion of the powdered root was well boiled with water, and the liquid poured off, the residue was again subjected to a similar process, and the liquids mixed and evaporated to one half. The decoction thus obtained was of a brown-red colour, with a slightly bitter taste, and peculiar odour. I then divided the liquid into three parts and proceeded as follows:—

The first part was evaporated to dryness, and the residue treated with water slightly acidulated with sulphuric acid. To different portions of the liquid thus obtained I then added the usual reagents used when testing for alkaloids, namely, phosphomolybdic acid, iodine in iodide of potassium, iodohydragyrate of potassium, and ammonia. In each case, after the test tubes containing the liquid had been set aside for three or four hours, a precipitate was obtained.

The second part was evaporated to dryness and treated with alcohol and the resulting solution after filtration was left to evaporate spontaneously, but I was not able to detect the presence of any crystalline matter even under the microscope.

The third portion was treated with reagents, and gave the following results:—

Ferric Acetate.—Dark green at first, gradually changing to brown, and depositing a precipitate.

Iodine.—Not any blue coloration.

Acetate of Lead.—Dirty brown precipitate.

Fehling's solution.—Reduced by boiling.

These results although indicating the presence of some alkaloid were certainly unsatisfactory, and all further attempts that I made towards the preparation of a definite crystallizable principle from the aqueous decoction were abortive, apparently owing to the presence of some resinous material which prevented crystallization.

A portion of the aqueous decoction was next treated with solution of subacetate of lead, until it ceased to precipitate; the precipitate was collected, washed, suspended in water, and decomposed by passing sulphuretted hydrogen through the liquid. This, on evaporation, left behind a strongly acrid reddish-brown extract, which on treatment with water yielded its acridity to that solvent, leaving a mass which gave indication of containing some variety of tannic acid, but the quantity was not enough to allow me to fully determine its constituents, and the small portion of original material that I had prevented me from repeating that process.

I then tried exhaustion with dilute acid, and, on the addition of alkali, a precipitate was obtained, which, however, proved to be totally insoluble in either of the following reagents, viz., alcohol, ether, chloroform, benzol, bisulphide of carbon; and, on further continuing its examination, I found it to consist of phosphates of magnesium and calcium. The marc left after exhaustion with dilute acid was of a bright red colour, proving it to contain some principle that was reddened by acids.

From the behaviour of the aqueous decoction with iron salts, I concluded that the root contained a variety of tannic acid, and some extractive matter, which possibly prevented crystallization of the entire principle, and I then tried the following process in hopes of at last obtaining some definite result:—

Half a pound of the finely powdered root was mixed with two ounces of slaked lime, and made into a thin paste with water. It was then evaporated to dryness over a water-bath, and afterwards exhausted with strong alcohol. Sulphuric acid was then added to acid reaction, and the resulting precipitate of sulphate of calcium filtered off. The alcohol was then distilled off, and the remaining liquid set aside. After some time a light coloured amorphous deposit separated out, which, when dissolved in spirit, gave the reaction for the alkaloid, and had a bitter taste; the quantity was, however, too small to decide anything definite about it.

A portion of the liquid from which the deposit had settled was treated with ammonia and boiled; this also give a precipitate, which, on solution in spirit, gave results as before.

A second portion of the liquid was then diluted with water, when a precipitate of dark resinous material was obtained. This dissolved in spirit with a magnificent red colour, which was destroyed on the addition of alkali and reddened again by acids, thus showing it to contain or to be the colouring matter of the bark.

These experiments prove that Carnauba root does contain an alkaloid, but that it is present in so small a quantity as to render it imperative to work on large quantities of material for its successful isolation. This I hope to be able to do at some future time when the supplies of the root are more plentiful, which time, according to Messrs. Symes, is not far distant.

Carnauba root also contains an acrid resinous body, a red colouring matter, a variety of tannic acid, and I think a small portion of volatile oil.

1, Devonshire Terrace, Marloes Road, Kensington, May 24th, 1875.

FLUORESCENCE AS A MEANS OF DETECTING ADULTERATION.*

BY C. R. C. TITCHBORNE, PH.D., F.C.S.

The following note will be interesting as illustrating how the fluorescence of any substance may be used for its detection in the presence of a non-fluorescent substance:—

About seven years ago, I made use of this phenomenon for the detection of turmeric when present in mustard in a report upon the commercial aspect of that substance.†

Lately it has been referred to, by one of the public analysts in England, as a method by which turmeric may be detected, and as it is so extremely delicate in its results, and yet so easy of application, I have thought it desirable to draw attention to the general principles upon which this phenomenon of fluorescence may be used for such purposes, and also with the view of laying claim to the idea.

If the adulterant is fluorescent, and the substance into which it is introduced is non-fluorescent, we have at once a ready means of examining any number of samples with much more delicacy than the usual chemical reactions will give. Thus, let us take the one to which we have already referred, the mustard of commerce.

The seeds of the black or white mustard yield a yellow, colouring matter, soluble in spirit of wine, which is devoid of fluorescence. Turmeric is always present in the inferior qualities of this condiment because the actual adulterant is wheaten flour or rice, the turmeric being necessary to bring the white adulterant up to the same shade as the ground mustard seeds, therefore the samples vary from 0·5 per cent. to 0·05 per cent. of turmeric. Now, with such minute quantities of turmeric the akaline test is very unsatisfactory—in fact, all chemical reactions are unsatisfactory—when dealing with such a minimum of adulteration.

But the great elegance of this fluorescent test consists in the fact that, within reasonable limits, *the more dilute the solution the more strongly* does the fluorescence test come out. The non-fluorescence of the colouring matter of all substances that are adulterated with a fluorescent substance should, in the first instance, be exactly and scientifically determined. This is easily done by any one who has the necessary arrangements. In the case of the mustard yellow, Mr. H. Draper kindly examined it for me, by the light of the spark formed between two steel wires (such a spark being the best for the purpose).

The steel points were placed in connection with a four-inch intensity coil and a small leyden jar was interposed in the circuit. The battery used consisted of three Groves elements. In examining by this method, ordinary glass vessels must be discarded, because even the strongly marked fluorescence of turmeric is more or less masked by the blue fluorescence of the glass.

In a quartz cell (two plates of quartz in a frame of gutta percha), these observations can be carried on with the greatest accuracy. Mr. Draper's observations prove that, whilst the colouring matter of the true seeds gave no fluorescence, the presence of so small a quantity of turmeric as ·005 per cent. could be readily detected.

Before we are justified, however, in using this phenomenon as the test for the presence of any substance, it is necessary to put it to a crucial examination, such as that detailed above, to find out how far the particular substance under examination is capable of giving fluorescence. But it is not at all necessary that we should submit it to the light of a spark in the practical application of the test. The fluorescence of an ordinary white glass flask is not observable under the ordinary diffused light of a laboratory, but the ordinary fluorescent substances (so called) are easily recognized under such conditions. It is only necessary therefore to form a tincture of the substance to be examined. The observation of Mr. Horner,‡ who finds

* From the 'Proceedings of the Royal Irish Academy.'

† *Medical Press and Circular.*—"Report on the Adulteration of Mustard." Vol. viii. New Series.

‡ *Philosophical Magazine*, Sept., 1874. See before, p. 282.

that fluorescence is wonderfully developed by castor oil, may be made use of with great advantage. A drop of castor oil that has been passed through adulterated mustard, upon a filter, appears green when dropped upon a black plate in ordinary daylight. If the mustard is pure, no coloration will be perceived. I have met with some specimens of "saffron" (the stigma and style of *Crocus sativus*) which give a fluorescence. They were evidently adulterated, because the flowers of saffron give no fluorescence. This saffron is a most expensive drug, and is therefore very liable to adulteration.

CHLOROFORM AS A TEST BETWEEN CHEMICAL AND PHYSIOLOGICAL FERMENTS.*

BY A. MÜNTZ.

The difference between ferments endowed with life and ferments consisting of a nitrogenous non-organized substance has been long established. Dumas has applied to the latter the characteristic term, "ferments non reproductibles;" they have, in fact, nothing characteristic of life, and are no more capable of multiplying than any other definite chemical substance. The common denomination applied to these two classes of agents of transformation cannot, therefore, be justified by the similitude of their mode of action upon substances subject to their influence.

It is sometimes difficult, in the presence of certain transformations, to decide whether there is or is not an intervention of organized beings, and the doubt cannot always be cleared up by microscopic observation, since there are living organisms which, either through their smallness, their resemblance to non-organized corpuscles, or the value of their index of refraction, escape the eye of the microscopist. One character sometimes forms a distinguishing mark between these two kinds of fermentations, but it is rather uncertain. Ferments endowed with life have their maximum of activity at a temperature varying between 25° and 40° C., whilst the generality of chemical ferments have this maximum situated sensibly higher, at a temperature where life is only with difficulty manifested. As a certain interest attaches just now to the distinction between those two orders of phenomena, confounded under the name of fermentation, the author has sought for an agent which will allow of their being clearly distinguished. In a memoir recently presented to the Academy of Sciences, he states that chloroform entirely fulfils the desired conditions: because it prevents absolutely all fermentation concomitant with life, whilst it is absolutely without influence upon the chemical class of ferments. The experiments upon which the author has based his conclusions appear to admit of a wider application.

(1) 200 cubic centimetres of milk with 5 c.c. of chloroform added, remained four months without curdling; no organism appeared in it. The butter was partly dissolved in the chloroform and precipitated with it to the bottom.

(2) 200 c.c. of fresh wine, with 2 c.c. of chloroform added, remained two months, at a temperature of 25° to 30° C., without undergoing ammoniacal fermentation; no organisms appeared in it.

(3) 10 grams of cane sugar, dissolved in 200 c.c. of water, in the presence of chalk, cheese, and 3 c.c. of chloroform, did not manifest the lactic fermentation at the end of four months; no organism was formed in the liquor.

(4) Flesh, gelatine, starch mucilage, and other alterable substances, in the presence of water and a small quantity of chloroform, were preserved upwards of three months, notwithstanding they were submitted to a temperature of about 30° C. No living being, animal or vegetable, was formed in the liquids.

(5) The alcoholic fermentation of sugar in the presence of beer yeast was completely arrested from the moment chloroform was placed in contact with the solutions.

The above experiments showed that the fermentations concomitant with life are not manifested in the presence of chloroform. Those that follow show, on the other hand, that chemical fermentations are neither prevented nor retarded by the same agent.

(1) 2 grams of dry malt, containing originally 0·05 gram of glucose, were brought into contact with 40 c.c. of water and 5 c.c. of chloroform. At the end of fifty hours there was formed 0·52 gram of glucose. In a parallel experiment without chloroform there was developed in the same time 0·54 gram of glucose.

(2) 10 grams of bitter almond meal, containing originally 0·006 gram of hydrocyanic acid, were placed in contact with 300 c.c. of water and 5 c.c. of chloroform. At the end of seventy hours there was developed 0·032 gram of hydrocyanic acid. In a parallel experiment, without chloroform, exactly the same quantity of hydrocyanic acid was developed.

(3) Some very liquid starch mucilage, containing originally about 0·915 gram of glucose per 100 c.c., was brought into contact with saliva and a considerable quantity of chloroform. After fifteen hours the liquid contained 0·120 gram of glucose per 100 c.c. The same mucilage, without chloroform, yielded with saliva 0·110 gram of glucose in the same time.

(4) Flour of mustard seeds, which contained only traces of the oil, in contact with water and chloroform developed an odour as strong as that with which pure water was used.

(5) 100 c.c. of a 5 per cent. solution of cane sugar marked in the saccharometer 33·0 to the right. Forty-eight hours after the addition of 3 grams of yeast and 5 drops of chloroform, this liquor, without the disengagement of a single bubble of carbonic acid, was almost completely inverted, marking at that time 9·5 to the left. In this experiment therefore the yeast produced its chemical action—inversion—due to a soluble matter that it contains which is analogous to diastase and its congeners; but it did not produce the alcoholic fermentation, which is a physiological action, concomitant with life.

Although in the course of his researches the author did not study in a special manner the symptoms of anæsthesia in the lower organisms, he found that after beer yeast had been under the influence of chloroform for several hours, it never appeared to resume its action upon saccharine matters with the same intensity when the chloroform had been removed. The lactic ferment appeared more capable of recovering its ordinary powers. Prolonged contact with the chloroform induced death.

M. Müntz suggests that this property of chloroform will permit the study from a fresh point of view of virus and other matters of animal origin, which are apt to give rise to disorders in the animal organism, since it would be possible by means of chloroform to distinguish between the virus which appears to act in the manner of diastase and its analogues, and the altered liquids producing the symptoms of septicæmia which were attributed to vibrions.

PHARMACISTS AS SCIENTIFIC INVESTIGATORS.*

BY BARON F. VON MUELLER, PH.D., M.D., F.R.S.

You are all so well aware of the functions expected form pharmaceutic science as one of the main auxiliaries of medicine that it might appear superfluous to dilate at all on the professional positions and any of its duties, which are devolving on you, and are to be maintained and elevated by you. At all events it might be most appropriate, on this first occasion of my meeting you, to encourage your progress by a few words on the great services rendered in times past to the natural sciences by some of

* Lecture delivered before the Victoria Chemists' Assistants' Association.

those celebrated men who arose from the same profession as your own. In instancing some of the discoveries which emanated from the study and laboratory of pharmacy we cannot go back to times when no strict limitation as yet existed of pharmacy as a distinct profession, when, indeed, the investigation and preparation of chemical substances and organic compounds for therapeutic use formed an integral ordinary part of the medical practitioner's work. Among those who, in the early days of a distinct recognition of pharmacy, distinguished themselves prominently was Marcgraf, a Prussian gentleman, who, about 120 years ago, discovered magnesia and alumina, and first showed the identity of beet and cane sugar (1747), perhaps little foreseeing at the time what an enormous influence this discovery would exercise in generations afterwards by raising a local supply of sugar in countries far outside of the tropical zones, and by providing thus also additional means for the rotation of crops through most nutritious stable food, and for facilitating the due maintenance of the fertility of any arable soil. Soon subsequently arose a still greater genius in pharmaceutic science, Carl William Scheele, a German by birth and descent, a Swede by fame. While an apothecary's assistant in Malmö and Stockholm he discovered fluoric, boracic, hydrothionic, tartaric, citric, and oxalic acids. He analysed first the constituents of bones. In Upsala, still merely an assistant, he became acquainted with the great renovator of zoology and phytology, Linné, and also with Bergmann, so famed for his extensive analyses of minerals and crystallographic researches on them, and here (about 1774) it was, where he made the important discovery of chlorine, solely and also independently of the British divine Priestley, and Lavoisier, the latter soon slain as a victim of the atrocities of the first French revolution, while Priestley encountered the furious hatred of fanaticism and jealousy, at a far more recent time than either Galileo, Brahe or Kepler, and was indeed obliged to take refuge in the transatlantic states. Scheele also discovered nitrogen, before he had even established a pharmaceutical business of his own, which took place at the age of thirty-five, and then followed his discovery of baryta, manganese, prussic acid, and some other most important chemical substances. His luminous career, however, was cut off at the early age of forty-four. Some of the researches of Scheele, and subsequently of Davy, led to the first steps towards photography. Vauquelin, who may be regarded as the founder of the qualitative organic analysis, was at first a pharmaceutist; his great countryman, Fourcroy, who was the son of a chemist, had the merit of introducing the new weights and measurements in France, and also of improving vastly chemical nomenclature. Chaptal, born in 1756, passed from the pharmaceutical to the medical career, was minister of home affairs under the first Napoleon, and was raised by Louis XVIII. to a peerage as Count Chanteloup, in acknowledgment of his great chemical discoveries, so well applied to industries and agriculture. Dumas, born in 1800, an ornament to the science of this century, was first a pharmaceutical chemist of Alais. We owe to him many essays on organic chemistry, atomic weights, substitutional proportions, and other chemical compounds; he also was minister of France, holding the portefeuille of trade and agriculture for two years. He has given us a great work, 'Traité de Chimie appliquée aux Arts,' in eight volumes. Had he never done anything else than drawing Pasteur into his luminous path, he would deserve our thanks for all time. I must pass on briefly to other great Frenchmen, such as Pelouze, Pelletier, and Brogniart, who were by descent or early occupation connected with the pharmaceutical profession; Pelletier being the discoverer of quinine and many other alkaloids. Brogniart still adorns the science of France, and became the principal founder of vegetable palæontology since the earlier part of this century. Of his friendship, and that of another leading palæontologist of this age, the venerable Gœppert of Breslau, who also was active in the pharmaceutic profession during his earlier years, I may well be proud. Forchhammer, in the duchy of Schleswig, was brought up for the pharmaceutical career. A generation afterwards I spent several years in the very house in which this famed geologist and oryctologist received his first education for the natural sciences. His extensive comparative analysis of seawater, also of many algæ, may be known to many in this room. He was Sir Roderick Murchison's stronghold when the latter investigated the geology of Scandinavia. Oersted, the friend of Forchhammer, the brother of a Danish prime minister, the illustrious discoverer of electro-magnetism, was the son of a pharmaceutic chemist and passed himself through the years of pharmaceutic apprenticeship; he even conducted for some time a pharmaceutic business of his own. He was the founder and first director of the Polytechnic School of Copenhagen, and an extensive and ingenious writer on the natural sciences in relation to religion and poetry, not to mention the various original contributions towards physical and chemical science. It is a pleasing recollection to me to have met this leading discoverer and also Forchhammer, at the meeting of the German Association of Medical Men and Naturalists, held in Kiel, in 1846. In Britain also arose some brilliant spirits through early though sometimes brief engagements in the pharmaceutic career, viz., Sir Humphry Davy, who acted as assistant to a surgeon and chemist at the commencement of his studies, whereby probably the first impulses to his investigations were given, although they soon extended to physiological subjects, such as respiration. Without him we might not have had the early discovery of the metallic bases of the alkalies in 1807, nor his safety-lamp for mining, nor his numerous applications of chemistry to agriculture, nor his almost poetic teachings; and more, perhaps, no Faraday would have guided us onward had it not been for Davy.

Sir David Brewster, great through his labours in optics, the founder of the British Association, first, also, if my memory carries me safely, for on it I must mainly rely in this address, imbibed his love for the sciences which he adorned while in the modest occupation of the pharmaceutic *atelier*. Baron von Liebig commenced his world-famed researches in a pharmaceutic laboratory at Heppenheim, where he worked for about a year; and perhaps the great worker through fully half a century, for the lasting benefit of mankind, would have been lost to us had not mere chance brought him first, though very briefly, to your own profession. I need not dwell here on his immensely extending organic chemistry, which through him passed into a new era, while through the practical applications of his inventions agricultural, physiological, and technological chemistry passed also into a new state. I am proud to possess several letters on scientific subjects, addressed to me by this great man. The family of the Gmelins might be regarded as almost a pharmaceutic one through several generations. I cannot in these cursory remarks refer to many of the very numerous men of science, which sprung from this family. One of them was the celebrated traveller, Samuel Gmelin, who went with Pallas, Güldenstedt and Lapuchin, for the advancement of natural history, through so much of Russian Asia, under the enlightened auspices of the Czar, from 1733-43. George Gmelin traversed with Behring much of Siberia, the results being lasting works on the fauna and flora of that wide tract of country. John Gmelin issued the thirteenth edition of Linneus' 'Systema Vegetabilium,' though engaged also as professor of medicine and chemistry. Ferdinand Gmelin advanced pathology much in the first half of this century. Christian Gmelin is the great chemical author of more recent date. Leopold Gmelin stands also prominent among the chemists of the century. Carl Gmelin published a large work on the flora of the Grand Duchy of Baden. Perhaps still more familiar to us here are the works of Heinrich Rose on analytic inorganic chemistry; he followed in the first instance the profession of his father and grandfather, who were pharmaceutic apothecaries. Gustav Rose, the brother of the above-named famed analyst, has widely advanced mineralogy, and was with Ehrenberg the companion of Baron von Humboldt in his travels through Russian Asia. Buchner, the disciple of Trommsdorf, was one of those who raised pharmacy to a science; he conducted for many years an important journal of pharmacy, originating from his adoption of your profession. Poggendorf, born in Hamburg, entered also the pharmaceutic career, through which many discoveries in chemistry and galvanism took place. As editor of the 'Annals of Physics and Chemistry,' from 1824 to 1867, he issued the colossal series of 134 volumes.

Pettenkofer, educated by his uncle, an apothecary at Munich, was for a long time pharmaceutic chemist to the royal family of Bavaria. We owe him the best method of obtaining gas from wood, researches on the cholera-poison, on ventilation and on important sanitary measures. Wittstein, whose translated works on the preparation of chemicals used in medicine will be in the hands of most of you, embraced also your profession. A translation of his meritorious new work on organic analysis and on the chemical constituents of plants, is prepared by myself, and would ere this have appeared, had fair support been given to my position among you in this colony during late years.

In illustration of what has been done by the profession of pharmacy for chemical and allied sciences, I have singled out these few representatives among those who advanced leadingly on that path of discovery; many others have toiled along, but as may be imagined, pharmaceutic gentlemen of high education have vastly promoted also other branches of knowledge. As might be supposed from their peculiar training, they have much advanced botany and also occasionally zoology. In both directions for instance Retzius, one of your profession, was active at Lund during the end of the last and beginning of the present century. He left his fame as an inheritage, well maintained by three sons, all professors of medicine, and distinguished for literary attainments. Ecklon, who lived for some time in the town of Husum, where I spent part of my youth, and who for many years was a chemist's assistant in Northern Germany and at Capetown, has rendered largely known the vegetation of Capeland, Caffraria, Hottentot Land, and other parts of South Africa, not merely as an exploring traveller, but as a phytological writer also. Rabenhorst, of Dresden, for forty years a persevering and successful mycologist, was long under engagements simply as an apothecary's assistant. Schacht, celebrated for his anatomic and other microscopic investigations concerning plants, made some of the first discoveries, which drew Schleiden's attention to him, in spare hours, at a chemist's shop.

Nees von Esenbeck, a meritorious botanic writer, was first in active service as a pharmaceutist. Martius, the great Brazilian traveller and naturalist, the author of numerous works, grandest among them that on palms, was the son of a pharmaceutic gentleman in Bavaria, and his brother, while continuing his father's business, became a leading author on materia medica. His friendship will not be oblivious to my memory. Among the three greatest of living bryologists, two are pharmaceutic chemists, namely: Hampe of Blankenburg, and Mitten of Hurstpierpoint in Sussex; both remained true through a long life to their adopted profession. Of the three living greatest of algologists, also, two are pharmaceutic gentlemen, namely: Kuetzing of Nordhausen, and Sonder of Hamburg; the latter, one of my oldest scientific friends, continues to conduct his original business up to this time, and it is therefore most praiseworthy that he was able, so circumstanced, to elaborate and publish, in co-operation with the late lamented Dr. Harvey, three large volumes of the flora of South Africa. But where am I to pause? There are numerous others, whose noble example should emulate you to raise here also the pharmaceutic standing. The strides of progressive knowledge have given pharmacy a place among the sciences; it is far more than a mechanic's art, if we view it in all its true bearings. An association, such as you have so thoughtfully formed, is well calculated to bring your profession to a deserving recognition. Well may you also aid here in progressive science, where a new country, with numerous of its latent resources, affords you multifarious opportunities to enter the field of independent discovery promisingly for success.

THE OCCURRENCE OF ORGANIC FORMS IN CONNECTION WITH CONTAGIOUS AND INFECTIVE DISEASES.*

BY J. BURDON SANDERSON, M.D., V.P.R.S.,

Jodrell Professor of Physiology in University College, etc.

LECTURE III.

(*Continued from page 870.*)

There are two contagious diseases besides small-pox, in respect of which there is reason to suppose that specific organic forms exist either in the blood or in the affected tissues—namely, relapsing fever and splenic fever. I propose to take splenic fever first.

Splenic fever is a malignant highly contagious disease of cattle, distinguished by the extreme rapidity of its course and fatal termination. It is interesting to us on account of the fact that it is characterized by the existence in the blood of organisms which, from the investigations of trustworthy observers, seem, though like common bacteria in form, to have such marked peculiarities of their own, that they may be regarded as specific. These bodies were discovered in 1855, or perhaps earlier; but their significance is still matter of dispute, there being great difference of opinion (even among those who admit that they are characteristic of the disease) as to the part they play in the morbid process.

The disease may be communicated by any means which involves the transference of a portion of the blood of a diseased animal to the living tissue of an animal previously healthy. It is not known that it can be propagated by any other way; for animals kept in the closest proximity to diseased ones, and placed under the most favourable conditions for infection through the air, are not infected.

The most striking feature of the disease is its extremely rapid progress and its short duration: in the so-called apoplectic cases, a few hours; in the more ordinary ones, a day or two. A sketch may be given in a few words of the disease as it presents itself in acute cases in cattle. An animal, which perhaps for the previous day has declined food and shown signs of general disturbance, begins to shudder and to have twitches of the muscles of the back, and soon afterwards becomes weak and listless. In the meantime, the respiration becomes frequent and often difficult, and the temperature rises to three or four degrees above the normal; but soon convulsions, affecting chiefly the muscles of the back and loins, usher in the fatal collapse, of which the progress is marked by complete loss of power of moving the trunk or extremities, diminution of temperature, mucous and sanguinolent alvine evacuations, similar discharges from the mouth and nares, and death. In the horse, the disease presents similar characters, but is much less acute. The local affection is more frequently recognized during life, so that the case is often recorded as one of "acute splenic tumour."

Of the phenomena revealed by dissection, those which relate to the blood, to the circulatory and lymphatic systems, and to the spleen, are by far the most important. In the blood, the colourless corpuscles are increased, especially in the horse. In the mucous membranes, general infiltration is one of the most marked results of the disease. In cattle it is excessive, and affects the whole course of the intestine, the cavity of which is found

* Lecture delivered at Owens College, Manchester; reprinted from the *British Medical Journal.*

to be full of sanguinolent transudation. In the horse it localizes itself in the stomach and duodenum, and presents itself in the form of circumscribed inflammatory tumours or thickenings of the mucous membrane. As, in these tumours, the inflamed tissue dies in the middle and sloughs out, leaving an ulcer, they are called carbuncles. The ulcers are called "typhous ulcers," and the whole disease in the horse is often designated "typhus."

The discovery that in the blood of animals affected with splenic fever rod-like bodies are found in the liquor sanguinis was first, I believe, made by Pollender, who, in the year 1855, described them as "fine, apparently solid, straight unbranched objects." He stated that they possessed no proper motion, differing in this respect from ordinary bacteria, leaving the question of their nature, as well as that of their relation to the contagion of the disease, open. A year or two after the publication of Pollender's paper, Brauell published the first of his very extensive series of researches on the contagion of splenic fever, in which he not only confirmed Pollender's discovery, but, by experiments in which he communicated the disease to animals under a great variety of conditions, acquired for pathologists the greater part of the accurate knowledge they now possess on the subject. He contented himself, however, with demonstrating that the organisms found in the blood in splenic fever were characteristic of the disease, without maintaining that they were, or that they were not, the *causes* of its virulence; and, indeed, was disposed to attribute more importance to them as diagnostics than as agents in the morbid process.

Three years later, the bodies in question were rediscovered by Delafond and Davaine, who, in claiming a priority which did not belong to them, no doubt did so in ignorance of the good work that had already been done in Germany. The existence of the rods as a characteristic of the circulating blood in animals affected with splenic fever, is a fact now admitted by all pathologists who are conversant with the disease. It is, however, remarkable (and at first sight difficult to understand) that many observers have expressed doubts as to their being organized living beings. Thus, Leisering at first took them for fragments of fibrin or for bits of tissue; others thought that they were blood-crystals. The statement made by Professor Bruckmüller of Vienna, and repeated by others, that Virchow at one time regarded the bacteria of splenic fever as blood-crystals, appears to be an erroneous one, founded on a misquotation of an oral communication.

The rods have been most carefully studied by Bollinger in his recent 'Researches in Comparative Pathology.' Each rod is about as long as the width of a blood-corpuscle. Along with the rods spheroids can always be found, which are no doubt forms of the same organism—parts of the same continuous development. As regards their structure, examination with high powers shows that each rod is made up of spheroids, each spheroid consisting, like an ordinary micrococcus, of a central darker part with a more transparent envelope. The most remarkable fact relating to them is, that they disintegrate rapidly from the moment that the blood becomes putrescent. As they disappear, the actively moving rods and spheroids, which indicate the commencement of the septic process, take their place, but there is no continuity of development between the two kinds of organisms.

The principal source of doubt as regards the part played by the rods in the contagious process of splenic fever has been the observation first made by Brauell, that, in the early stage of the disease, no rods are found in the blood; and that nevertheless such blood possesses the contagious property. This question has been lately investigated very fully by Professor Bollinger, on the basis of experiments made expressly for the purpose. From the results of these experiments, it seems certain, (1) that blood without *rods* may yet be contagious; (2) that animals infected by it contain the rods in their blood in as great numbers as others. Are the rods, therefore, intimately associated with the contagious material—the contagium? or is their appearance a merely collateral phenomenon—a symptom of the disease?

(*To be continued.*)

THE IRISH PHARMACY BILL.

DEPUTATION TO THE CHIEF SECRETARY FOR IRELAND.

The Sub-Committee appointed by the Council of the Pharmaceutical Society to confer further with Sir Michael Hicks-Beach regarding the Irish Pharmacy Bill, with especial reference to his suggestion for an *ad eundem* qualification, had an interview with him on Thursday, and informed him of the views entertained by the Council as expressed by the petition presented to the House of Commons, and handed him the following paper upon the subject of the proposed *ad eundem* qualifications:—

"Regarding the suggestion in favour of degrees or examinations *ad eundem*, it would appear that those which exist do so exist only at the universities, they being ancient institutions governed by similar laws and administered by persons appointed by the same authorities.

"It is practicable, and would appear to be free from objection, for two separate Societies to approach something like arrangements for *ad eundem* degrees by arranging that persons holding the degree of either shall be admitted to the highest examination of the other without having to proceed by stages; but for an arrangement of that kind further Parliamentary powers are not required by the Pharmaceutical Society of Great Britain, because the existing charter and Acts confer adequate powers, and the bye-law, No. 16 of section 10, sufficiently provides for the case, so that the Council of the British Society could arrange with the Council of the other Society for those persons who may hold the certificates of the one Society being admitted to the benefit of that bye-law on the one hand, and a similar bye-law on the other hand.

"*Ad eundem* arrangements should be a growth or fruit of mutual regard, and mutual regard cannot prevail between an existing body and one which may or may not come into existence—the body which may arise may grow into public esteem, and thus reciprocal feeling of respect and regard may arise (they cannot be created by Act of Parliament)—when they exist, the natural outgrowth may be expected."

Sir Michael Hicks-Beach expressed a determination to carry the Bill in its integrity, subject only to a modification to be devised by him, having for its object to exclude all persons who may be placed on the existing register in right of being on the Irish Register, from participation in the funds of the Pharmaceutical Society of Great Britain. The petition of the Society against the Bill is printed on p. 978.

THE MIDLAND COUNTIES CHEMISTS' ASSOCIATION AND THE IRISH PHARMACY BILL.

On Thursday a special meeting of the Executive Council of the Midland Counties Chemists' Association was held at the rooms, New Street, Birmingham, to take into consideration the Irish Pharmacy Bill. Mr. T. Barclay, of Birmingham, presided. After a lengthy discussion it was unanimously resolved that the subjoined resolution should be sent to the following members of Parliament, namely, Messrs. Bright, Dixon, Muntz, Newdegate, Bromley-Davenport, H. Allsop, Walker, Bass, and S. C. Allsop. The resolution is as follows:—"That the proposed measure, in its present form, is prejudical to the interests of the public, and unjust to the chemists of Great Britain, as it would give undue advantages to Irish chemists who might desire to commence business in Great Britain, and, at the same time, mislead the public as to their qualifications. The Council would strongly urge the extension to the whole kingdom of the laws which now within Great Britain regulate the qualifications of chemists and also of the sale of poisons, and, therefore, earnestly request that you will oppose the Bill in its present form."

The Pharmaceutical Journal.

SATURDAY, JUNE 5, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE IRISH PHARMACY BILL.

DURING the past week, the proposed legislation affecting pharmacy has naturally occupied a foremost position. A great deal of the attention of Wednesday's Council was devoted to the subject, and throughout Great Britain a warm interest has been displayed, and numerous petitions have been presented to Parliament, generally in favour of the views entertained by the Council as those views appear by our report of the proceedings. Further, Mr. SALT has given notice that when the motion for the second reading of the Bill comes before the House he will move that it be read that day three months.

We are not aware of any petitions to Parliament from Ireland or elsewhere in favour of the Bill, and the only evidence of Irish interest in the measure of which any trace has become apparent has been the arrival of a deputation consisting of some eminent apothecaries (three licentiates of the Irish Apothecaries' Hall, two gentlemen from Belfast, and one from Cork) practising not as medical men, but as pharmacists merely, in fact, holding a position the same as that of a pharmaceutical chemist in Great Britain, whose views (so far as they have been expressed) appear to be in favour of an extension of the Society's operations to Ireland, with a limitation that no qualification below that of pharmaceutical chemist shall be recognized within that part of the United Kingdom.

The ways of politicians are mysterious to the uninitiated, but unfortunately it is the case that HER MAJESTY'S Government have introduced and therefore become somewhat pledged to a measure materially affecting British pharmacy, without any previous communication upon it with the Pharmaceutical Society of Great Britain, and so far as can be traced without the ascertained approbation of any medical body of either part of the United Kingdom.

The practical result of the latest interview with HER MAJESTY'S Chief Secretary for Ireland is that the right honourable gentleman takes a stand and has expressed a resolve in favour of "the Bill, the whole Bill, and nothing but the Bill," with a modification that is unimportant by comparison with the leading features of the Bill; for the practical result of it is that the existing Society having created and obtained within Great Britain the exclusive right to and, in a sense, a property in the title "pharmaceutical chemist," and having accomplished a great work which has materially benefited the country not only for the better health of its population but for the improvement of its foreign trade in drugs and chemicals, is through an enforced reciprocity with a possible Society, as yet nameless and non-existent, to have its work "watered" and embarrassed.

To a Society within Ireland, with its operations limited in sphere and confined to that kingdom, the Pharmaceutical Society of Great Britain cannot as a Society have objection, whatever may be the ideas of individuals upon the broad public question of expediency; but that the work which has been done within Great Britain should be imperilled and that the name or style, which has a value only through the action of the Society, should be appropriated appears to be a form of wrong against which every well-thinking man should use his utmost strength.

Those who know the objects and the work of the Pharmaceutical Society of Great Britain are well aware that its loftiest aim has been to advance scientific pharmacy by promoting an uniform system of education, and that associated with it there has been the object of the Benevolent Fund; and none within the pale of the Society have uttered a word against the generous extension of the Benevolent Fund as well as other objects of the Society to Ireland; but Sir MICHAEL HICKS-BEACH, whilst refusing the broad matters of principle pressed on his attention by the Society, has, out of his own sense of justice, said that he will so modify the Bill that the Irish Society and those holding its degrees shall not, as of right, place a hand upon the funds of the existing Society. We are reminded of SHAKESPEARE'S words, "He who steals my purse steals trash . . . . . but he who filches from me my good name robs me of that . . . . which makes me poor indeed."

For the cause of pharmacy it is to be hoped that some outspoken voice will come from Ireland in favour of right and against wrong; but however that may be, the Society has done and will continue to do its best for its mission, and it is for each member of the body within his sphere to bring an individual opinion and weight into the scale.

THE DRUGGING OF ANIMALS BILL.

THE Parliamentary Committee of the Council of the Pharmaceutical Society met on Thursday morning to consider the Bill introduced to the House of Commons by Sir JOHN ASTLEY, which proposes to render the administration of poisonous drugs to horses and other animals by unqualified persons a penal offence. A copy of the Bill will be found at page 981 of this Journal.

It will be seen that the third section goes far beyond the purpose of the Bill as set forth in the preamble, and applies not to the administering but to the selling of poisons, a proceeding perfectly unnecessary, as the selling is already fully regulated by the Pharmacy Act. But although Sir JOHN ASTLEY has taken the trouble to re-enact the 17th section of the Pharmacy Act, and to make Schedule A of that Act the foundation of his Schedule of Poisons, he has, by the construction of his Bill, made the more stringent provisions of registration of sales and knowledge of purchaser apply alike to all poisons. It is needless to say how this would inconvenience not only the sellers, but the public, if applied to Part 2 as well as Part 1 of the already established schedule; but when we look through the newly proposed poisons the mischief becomes so glaring that it must surely be apparent to every man who knows anything about the uses of the mineral acids and metallic salts. All additions to the Schedule of Poisons must rest with the Council of the Pharmaceutical Society, and have the approval of the Privy Council, and this interference in the matter is both uncalled for and likely to produce confusion. A paper strongly setting forth these views was drawn up by the Committee, and the Vice-President and Mr. SANDFORD, accompanied by the Assistant-Secretary, Mr. RICHARD BREMRIDGE, proceeded to the Home Office, and laid it before Sir HENRY SELWYN-IBBETSON, who promised the attention of the Government to the matter.

The Bill was put down for second reading on Thursday, but did not come on. Sir W. HARCOURT has given notice to oppose it.

THE TRUE GAMBOGE PLANT.

ABOUT ten years since the late Mr. DANIEL HANBURY, in a paper read at an Evening Meeting of the Pharmaceutical Society, stated that from an examination of numerous specimens of a plant which had been introduced into Singapore from Siam as the true gamboge-tree, he had come to the conclusion that it was a variety of *G. Morella*, differing from the typical variety in having pedicellate instead of sessile male flowers. This variety he described and figured in the *Transactions of the Linnean Society*, as *Garcinia Morella*, var. *β. pedicellata*, and it is quoted as the source of the official gamboge in the British Pharmacopœia. In the recently issued volume of the 'Flora of British India,' however, the variety has been suppressed by the late Dr. THOMAS ANDERSON, who worked up the Guttiferæ, Mr. HANBURY's figure of the variety being quoted apparently as accurately representing the species.

Some further important contributions to our knowledge of this genus have nevertheless confirmed Mr. HANBURY's judgment, and Dr. HOOKER, who had been temporarily misled by Dr. ANDERSON's suppression of var. *pedicellata*, in a paper published in the last (April) issue of the botanical portion of the *Journal of the Linnean Society*, expresses an opinion that Mr. HANBURY's plant is so different in the habit of the male inflorescence from all the forms of *G. Morella* with which he has compared it that it should be regarded as being even specifically distinct. Its leaves also differ from those of all varieties of *G. Morella* in their more ovate form and larger size and the fruit is larger. Dr. HOOKER suggests that the species "should bear the name of *G. Hanburyi*, after our eminent pharmaceutist."

PHARMACY IN JAPAN.

FROM a note published in the *British Medical Journal* on the authority of the Dutch *Pharmaceutsch Weekblad* it would seem that the latest Western fashion in which Japan has indulged is an adulteration panic. It appears that with a view of preventing the adulteration of drugs imported from Europe a laboratory had been established by the Japanese Government in Yedo, another in Kiyoto, under the superintendence of Dr. DWARS, and a third at Osaka, under Dr. GEERTS, for the examination of drugs and the practical instruction of Japanese youths in pharmacy. The Japanese Government has also ordered that any druggist who has in his possession sulphate of quinine or iodide of potassium in an adulterated state shall be punished for a first offence by a fine of 50 yan, or about £5.

CONTINENTAL CONGRESSES.

THIS year's Congress of the French Association for the Advancement of Science will be held at Nantes, from the 19th to the 26th of August. Circulars have been issued inviting persons who desire to read papers before the Congress to communicate at once with respect to the subject upon which they wish to treat to one of the Local Secretaries, MM. COLOMBEL, LAENNEC and MALHERBE fils, of Nantes, or with M. GARIEL, Secretary to the Council, 76, Rue de Rennes, Paris.

On the 19th of September, the International Medical Congress for 1875 is to commence at Brussels, under the auspices of the Belgian Government. Of eight sections one is allotted to Pharmacology. The questions down for discussion in this section are—(1) The establishment of a Universal Pharmacopœia, and (2) Is it necessary to extend the employment in medicine of chemically definite immediate principles, and thus to multiply the preparations included in the Pharmacopœias? Some of the subjects of the other sections also will present points of chemical and pharmaceutical interest.

THE sum of £500 has been included in this year's Estimates as a salary for an Assistant Director of the Royal Gardens at Kew. The *Gardener's Chronicle* believes that Professor W. T. THISELTON DYER is to be appointed to the new office.

MR. GEORGE BENTHAM, F.R.S., the late President of the Linnean Society, has been elected a Corresponding Member of the French Academy of Sciences.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, June 2, 1875.

Present—Messrs. Atherton, Baynes, Betty, Bottle, Brown, Cracknell, Frazer, Greenish, Hampson, Hanbury, Hills, Owen, Rimmington, Robbins, Sandford, Savage, Schacht, and Williams.

Mr. Thomas Hyde Hills having been voted to the chair, the minutes of the previous meeting were read and confirmed.

Election of President.

The first business was the election of a President for the ensuing year, and a ballot having been taken, Mr. Hills was re-elected.

Mr. Hills, in thanking the Council for the honour it had conferred upon him in electing him for the third time, said he thought it was a bad precedent to elect the same gentleman for three years successively, except under very special circumstances, and he should have preferred that the choice should have fallen on some one else. However, he would place himself in the hands of the Council, though he hoped the same thing would not occur again.

Election of Vice-President.

On the first ballot, Mr. Savage obtained the largest number of votes, but he declining to serve,—a second ballot was taken, and Mr. Bottle was re-elected.

Mr. Bottle cordially thanked his fellow-members for the honour which they had quite unexpectedly conferred upon him, and said that in accepting this position for a third time he could only do so upon the express understanding that he would not accept re-election after the expiration of the present term of office.

Election of Treasurer.

Mr. Sandford said he had often acted as chairman on the occasion of the annual election of officers, and on more than one occasion he had known a treasurer to be elected without the formality of a ballot, when they had the services of a gentleman who appeared to be particularly qualified for the office. He would therefore propose that Mr. Williams be re-elected treasurer.

The motion was carried by acclamation.

Mr. Williams briefly acknowledged the compliment.

Election of Secretary and Assistant Secretary.

Elias Bremridge was re-appointed Secretary and Registrar, and Richard Bremridge, Assistant Secretary and Deputy Registrar.

Elections.

MEMBERS.

Pharmaceutical Chemists.

Draper, James William ....London.

Chemists and Druggists.

Bard, Henry ....Exeter.
Lambert, Thomas ....Bradford, Manchester.

ASSOCIATES.

The following having passed their respective examinations and being in business on their own account were elected "Associates in Business" of the Society:—

Minor.

Hodgkinson, Charles................London.

Modified.

Clark, John ....Sheffield.
How, Randal Edward ....Oxford.
King, Abraham.....................Dunstable.

The following having passed the Minor examination were elected "Associates" of the Society:—

Bridgewater, Francis Foster ...Deal.
Stanley, Thomas ....Alcester.

APPRENTICES.

The following having passed the Preliminary examination were elected "Apprentices or Students" of the Society:—

Glegg, John ....Edinburgh.
Jones, John ....Liverpool.
Minnitt, Walter ....London.
Neale, Edgar........................Faringdon.
Page, William Hawkins ....Colchester.
Prosser, Francis....................Milford Haven.
Shenstone, James Chapman......Colchester.
Wallbridge, Henry Alfred ......London.

Several individuals were restored to their former status in the Society upon payment of the current year's subscription and a fine.

John Herbert being duly registered as a pharmaceutical chemist was granted a diploma stamped with the seal of the Society.

The names of Henry Greasley, of 163, Blackburn Road, Accrington, Lancs., and John Jolliffe, of 10, Barandon Street, Lancaster Road, Notting Hill, were restored to the register of Chemists and Druggists.

The Conversazione.

Votes of thanks were unanimously passed to the Lords of the Committee of Council on Education, for their kindness in allowing the use of the South Kensington Museum for the Annual Conversazione; and to the official staff of the museum for their services on the same occasion.

Appointment of Committees.

Mr. Schacht suggested that a more efficient part in the work of the Committees could be taken by each member of the Council if more of the Committees met on the Tuesday afternoon preceding the Council meeting. He had alluded to this subject more than once before, but he was still convinced that an improvement could be made.

Mr. Robbins said the Finance Committee met on the Tuesday afternoon, but there was not one country member upon it.

Mr. Greenish said it was absolutely necessary to appoint a sufficient number of London members to carry on the business of the Society. He was very glad to see country members on the Committee, but if, as sometimes happened they only attended occasionally, they came quite new to the business, and instead of being an assistance were really a hindrance.

After some further observations from Mr. Williams, Mr. Savage, Mr. Schacht, and Mr. Atherton, the following Committees were appointed:—

General Purposes.—The whole of the Council. To meet as occasion may require.

Finance.—Messrs. Cracknell, Greenish, Hanbury, Owen, and Robbins. To meet at 3.30 o'clock on the day preceeding the meeting of the Council.

Benevolent Fund.—Messrs. Atherton, Brown, Frazer, Greenish, Mackay, Owen, Rimmington, Robbins, Sandford, Schacht, and Shaw. To meet at 5 o'clock on the day preceeding the Council meeting, as occasion may require.

Library, Museum, and Laboratory.—Messrs. Betty, Greenish, Hampson, Hanbury, Robbins, Sandford, and Williams, with power to add to their number. To meet the second Wednesday in the month at 11 a.m.

House Committee.—The same as Library, Museum, and Laboratory Committee. To meet as occasion may require.

Law and Parliamentary.—Messrs. Atherton, Baynes, Betty, Brown, Greenish, Hampson, Hanbury, Mackay, Owen, Rimmington, Robbins, Sandford, Savage, Schacht, and Williams, with power to add to their number. To meet at 6.30 p.m. on the evening preceding the Council meeting, or as occasion may require.

Mr. Robbins suggested that the work of the Law and Parliamentary Committee really belonged to the General Purposes Committee, which never met at all.

Mr. Hanbury thought Mr. Robbins' suggestion was a very good one, and that the Committee, consisting of the whole of the Council, might appoint a sub-committee to attend to parliamentary or any other particular business.

The Vice-President thought this could hardly be done under the bye-laws.

Mr. Brown said the Parliamentary Committee could appoint a Sub-Committee to attend to legal business or any other matter of detail.

Pharmaceutical Education.—On this Committee being mentioned,

Mr. Brown suggested that it would be better not to appoint it but to summon the General Purposes Committee when any question of education arose.

Mr. Schacht said there were several matters referred to that Committee which had not yet been reported upon. He did not know whether it was wise to abolish the Committee until that was done.

The Vice-President remarked that the Committee was already defunct, unless re-appointed, and could not bring up any report. If necessary, the matters referred to that Committee could be relegated to the General Purposes Committee.

The suggestion was then agreed to.

Evening Meetings.—The President, the Vice-President, the Professors, and the Editor were appointed a Committee to make arrangements for the evening meetings.

The President and Vice-President are *ex officio* members of all Committees.

Appointment of Editor and Sub-Editor.

Dr. Paul was re-appointed Editor, and Mr. F. Passmore Sub-Editor of the Journal and Transactions of the Society for the ensuing year.

Local Secretaries.

The Secretary said there were this year 311 towns entitled to elect local secretaries; 10 which previously enjoyed the privilege were not now eligible, not being parliamentary boroughs, and not having 3 resident members or associates in business; and there were 15 towns not on last year's list now eligible. There had been 12 changes by nomination, and in 131 towns there was no nomination, whilst in 4 towns the members had nominated persons not connected with the Society. He thought it was very desirable for the Council to nominate one or two gentlemen to go through the list with him, as it was rather an invidious task to undertake, in some cases names of persons having been suggested who did not appear eligible. For instance, for one town a gentleman was named who did not reside there.

Mr. Rimmington suggested that where the members in a town did not take the trouble to elect a local secretary, none should be appointed.

The Secretary said that was his feeling, but it was sometimes inconvenient to the Society not to be represented in particular localities.

On the motion of Mr. Sandford it was resolved :—

> "That the list of persons nominated as local secretaries now presented be referred to the Library, Museum and Laboratory Committee for completion, and that the Committee be requested to report thereon to the Council at its next meeting."

The Standing Orders.

The Vice-President bore testimony to the excellent manner in which the business of the Society had been managed in the committees during the past year, most of which he had attended. He said he did not remember one occasion on which there had been a delay of more than five minutes in order to form a quorum. He then moved that the standing orders for the regulation of the proceedings of the Council, a copy of which had been laid on the table, be adopted for the ensuing year.

Mr. Schacht said if it was agreeable to the Council he would now bring forward as an amendment the motion of which he had given notice:—

> "That members of Council having intention to introduce any motion of which notice has not previously been given, shall announce the same at the commencement of the day's proceedings."

If the amendment were approved it would, of course, be added to the standing orders. He would not detain the Council with a speech on the subject, his motion being founded on the principle that it was always desirable to know pretty well the business which was likely to come forward, in order that if the proceedings should be extended to an unusual length, those who were anxious to take part in any particular discussion would take care not to leave before it came on. It had been suggested by Mr. Brown that the motion would be more acceptable in the following form, which he was willing to accept :—

> "That no motion, unless in relation to subjects arising out of the minutes or introduced by the President, shall be brought forward unless previous notice has been given in the usual manner, or the intention declared at the commencement of the proceedings."

Mr. Frazer seconded the motion.

Mr. Sandford said it was competent to the Chairman to adjourn to the next meeting any motion of which previous notice in writing had not been given, and he feared that even in the modified form suggested the motion might be attended with inconvenience. For instance, a member might not be able to attend at the commencement of the business; he might, in fact, be attending to some matters of importance on behalf of the Society, and be unable to come in until 1 o'clock, and might then ask the Council to pass a resolution in reference to the business on which he had been engaged.

Mr. Frazer thought it hardly fair to the Chairman to impose upon him the invidious duty of postponing a discussion.

Mr. Hampson did not think the resolution at all necessary, as the standing orders provided for all emergencies. The President had authority to exclude the reception of any resolution if previous notice had not been given of it, or if it did not properly arise out of the business under consideration.

Mr. Schacht said cases had occurred in which resolutions had been passed of which no notice had been given.

Mr. Williams thought that in cases of grants of money notice of motion should always be given, but such had not invariably been the case.

Mr. Brown had had some difficulty with respect to this notice of motion. He could quite see that cases might arise, and no doubt had arisen, where such a rule would be of advantage, but on the other hand it might be found inconvenient in some cases, and on the whole he thought they had better leave themselves in the hands of the President.

The amendment on being put was lost.

Mr. Schacht said he would only now ask that the principle involved might be considered a part of their unwritten law.

The Vice-President thought that would answer the purpose.

Library, Museum and Laboratory.

The Committee reported that at its meeting held on the 12th of May, Professor Attfield had reported there had been 97 entries in his class since the commencement of the session, 53 being now at work. The Curator had reported that the average attendance in the museum for the past month had been—in the morning, 16; in the evening, 3; visitors in the morning, 1; evening, 1. He reported the reception of a fine specimen of iron alum from Mr. Morson, and also some fine specimens of Brazilian drugs from Messrs. Cyriax and Farries. The Librarian had reported that the average attendance at the library and conversation room had been—in the day, 22; evening, 8; conversation room, 5. The circulation of books had been

—127 in town; and in the country (to 25 places), 38. The Committee recommended the purchase of the following books for the library:—Bentley and Trimen's 'Medicinal Plants;' Sachs' 'Text-Book of Botany,' translated by Bennett and Dyer; and Normandy's 'Commercial Handbook of Chemical Analysis,' by Noad.

The report and recommendations were received and adopted.

Finance.

A report was read from from several members of Council who had acted as a Finance Committee, and sundry accounts were ordered to be paid. Some conversation ensued as to the indifferent quality of the refreshments supplied at the late conversazione by the contractor at the South Kensington Museum, when the Secretary stated that he believed it was open to the Council to go to any other contractor and make arrangements.

Mr. Robbins was very glad to hear it, for he had understood quite the contrary.

The Irish Pharmacy Bill.

The Secretary was about to read the minutes of a special meeting of the London members of Council called to consider this matter, when

Mr. Schacht asked if the matter had not been distinctly referred to the Parliamentary Committee to watch the Bill.

A considerable discussion ensued on the question whether the members who had met to take action in this matter had been the Parliamentary Committee or the London members of Council, and the Secretary also read the correspondence which took place with the Chemists and Druggists' Association of Ireland in the autumn of last year. He then read the minutes of what had taken place last month, including the deputation to the Chief Secretary for Ireland, a report of which has already appeared in the Journal, p. 951, and also a petition and circular which had been sent round to all the local secretaries in order to obtain signatures thereto.

Mr. Atherton moved, and Mr. Brown seconded:—

"That the report of the proceedings of the Special Committee on the Irish Pharmacy Bill be received and adopted."

Mr. Sandford moved an amendment, that the words "and adopted" be omitted. He could not help thinking that the Committee, whether regular or irregular, had taken a very strange proceeding, for, if he read aright the report of the deputation, they had broken faith with Sir Michael Hicks-Beach. Sir Michael had put before the deputation certain propositions, and it had promised to consider them, upon which he promised to suspend action until the deputation again saw him. He, therefore, thought the members of the deputation had behaved discourteously, to say the least of it, in sending out this petition, and that they ought to have suspended action until they had considered in council the propositions of the Chief Secretary for Ireland.

Mr. Hampson, as one who was present at the interview, said there was no understanding come to of the kind, but it was clear that the proposition of Sir Michael Hicks-Beach was of a very indefinite character and not sufficient to warrant a delay in opposition to the Bill. A question of policy had to be considered, time was pressing, and it was the duty of the Committee to carry out the resolution passed almost unanimously by the Council in October, and to oppose the Bill by all proper means.

Mr. Flux said the report of the deputation in the Journal, he thought, conveyed a slightly wrong impression by the full stop being inserted after the word "certainly" in the sentence where Sir Michael Hicks-Beach said he would not bring on the second reading on the Monday evening. It gave a more forcible impression than would follow from that gentleman's manner. More than that, after they left the room, he sent a message which seemed to convey that he had not given any distinct pledge on the subject. In one other point he thought the report slightly modified the expression, where it said that the establishment of a separate society for Ireland was a point upon which he should hardly think of giving way. His impression was that the Chief Secretary said "cannot give way."

Mr. Hanbury said that his memory confirmed that of Mr. Flux.

Mr. Williams said the messenger from Sir Michael Hicks-Beach came to him with a message that Sir Michael would be glad to see three or four members, as soon as convenient, to re-consider and talk the matter over again. He told the messenger in reply, that it would hardly, he thought, be right for a further deputation to wait on the Chief Secretary, until the Council had met and authorized their line of conduct. With reference to the petition and circular, he must leave the Solicitor to explain that part of the business.

The amendment was then put and lost.

The President was about to put the original motion, when

Mr. Schacht said he wished to have another opportunity of opposing it. It appeared from the motion which had been read, that the deputation had committed itself in certain broad phraseology to the principle that it would be desirable to extend the operation of the Pharmacy Act to Ireland, and to that he should offer the strongest opposition. If they could go back to the time when no Pharmaceutical Society existed in England, no one would have expected Parliament to place in the hands of any non-existing body the power of regulating the whole proceedings of pharmacy. Certainly, they would never have asked them to grant to A. B. or C. D., persons comparatively unknown, the power of declaring who should or should not carry on the business of pharmacy in England. The history of legislation in England did not take that form; but, first of all, there was a Society formed, and the great men, whom they all knew by name, associated themselves together, did a great deal of work, and gave a guarantee to the world that they were qualified to carry out the regulations which the Act of Parliament afterwards gave them power to enforce. But, until that was done, no government could have given such power into their hands; and yet that was the very thing they were going to propose to do in Ireland at present.

Mr. Williams said that was what they were opposing.

Mr. Schacht said that they were palpably endorsing the same thing in saying they were prepared to establish a Board of. Examiners in Ireland. There were not the materials there to carry on a society that there were in England or Scotland, and, therefore, to pledge themselves to at once extend the operations of this Act to Ireland was a step he could not sanction for a moment. The Committee had not contented itself with opposing what was wrong; if it had he should have been ready to endorse its action; but it had proceeded to enunciate not only for itself, but for the whole body, which for the moment it was supposed to represent, sentiments which had never been fully discussed in the Council or elsewhere, and certainly had never been adopted. He had heard two or three discussions upon this subject, which had always run in this direction, that if the Irish pharmacists were anxious that the provisions of the Act should extend to that country, then the Society was willing to discuss the question with them. It was always assumed that the Irish element generally was anxious in the matter, but Sir Michael Hicks-Beach stated most plainly, that the Irish pharmacists wanted, not to be connected with the British Society, but to have an independent one of their own. He thought the Committee had acted most unwisely in endeavouring not only to create a wrong impression as to the general feeling of English pharmacists, but in going to the extent of using the machinery of the Society, by sending out a petition and circular, asking to get it immediately signed by pharmacists throughout the country, and sent up "the day after to-morrow," thus endorsing views which had never been fully discussed. He thought such action was decidedly wrong, and he hoped the word "adopted" would not be recorded.

Mr. Savage could not agree with the view of Mr. Schacht on this matter. The apothecaries of Ireland were a great body, at present trying to gain ascendancy, and it seemed important that the Pharmaceutical Society of Great Britain should do all it could to protect pharmacists. For after all there had been a great many pharmacists in Ireland, who, although they were not numerically strong, had still some influence and power, and ought not to be placed under subjection to the apothecaries. The propositions emanating from the Society of Chemists and Druggists were for the most part good, and the question was, Should they, as a Society, desire to have the same influence in Ireland as they had in Scotland—whether there should be two bodies which might be antagonistic or not in harmony with each other, or whether there should be but one for the whole United Kingdom?

Mr. Hampson said Mr. Schacht objected that they knew nothing of Irish pharmacists, but it was these very Irish pharmacists of whom it was said they knew nothing who might come over to England under this Bill and claim the privileges of the Society. It was surely their duty to protect their own interests and to prevent such a Bill passing. They knew the danger of letting an obnoxious Bill get into Committee, and, therefore, they considered it the best policy to stop the progress of the Bill altogether, and to endeavour to bring about a better understanding both here and in Ireland by means of interviews with Irish pharmacists and others in order that a Bill might be framed for introduction hereafter which would satisfy both countries.

The Vice-President called attention to the formal resolution of the Council on the 7th of October last: "That it is desirable to extend the provisions of the Pharmacy Act to Ireland." He, therefore, considered the London members were carrying out the resolution of the Council in their opposition to the Irish Bill, and in all that they had done.

Mr. Schacht thought the general opinion was, supposing Irish pharmacists desired co-operation, then the Council was willing to meet them, and extend the Pharmacy Act to Ireland.

Mr. Williams said the Committee rather confined itself to opposing the present Bill, because it thought the Bill was one which could hardly be made satisfactory by any amount of manipulation. It was apparently intended by the Government not to form a society like their own, but a society of Government nominees, probably to receive payment from the State. It appeared to him the Government was to appoint a Board of Examiners who would practically be perfectly independent of the British Society—in fact his belief was that the nominees so appointed would probably be medical men—and yet men who were examined by such a Board would claim to come to England and be placed on the Register of Pharmaceutical Chemists. It was this which led him to urge that the Committee should oppose the Bill *in toto*. There ought to be either two societies mutually supporting each other, or they could extend the Pharmaceutical Society, under proper conditions, to Ireland. They were quite willing to have supported a society in Ireland if properly constituted, and if before placing their examinees on the English register there were some efficient control over the examination by the British Society; but until that was allowed they must oppose the present Bill. That was the view which the Committee impressed on the Chief Secretary. The petition had been adopted in deference to the views of the Solicitor.

Mr. Flux said he should certainly have regretted very much if any advice he had given after the return of the deputation to the Chief Secretary had led to a step which could have been considered by that gentleman as discourteous. He would always avoid everything of that character if possible, more especially with Sir Michael Hicks-Beach; but the grounds upon which he recommended the course pursued were these, that the legislative powers were with the Government, and not with the Society, and therefore they could not discuss abstract propositions in a legislative sense. They could only consider that which was actually before them, namely, the Bill as printed, which contained the vicious principles which had been pointed out by several speakers. The persons to be appointed as examiners were to be appointed by the Government, and the Society, when formed, was to have the power of pouring into Great Britain, not chemists and druggists but pharmaceutical chemists; whilst the preamble to the Bill went to show that what was wanted in Ireland, was a class of persons who should be compounders and sellers of medicine. In this state of affairs the formal resolution of the Council in Octo- last was come to, and the next question was how to give effect to it. It was evident the Society could not avoid considering the Irish question. After it had passed a resolution that it was desirable to extend the Pharmacy Act to Ireland, it seemed to him that the condition would be realized if Ireland were incorporated with the remaining portion of the United Kingdom (which was the natural state of things). It might be said that the best way would be to let the Bill go into Committee, and then attempt to modify it, and introduce such changes as were necessary; but it must be remembered they had no power of modification, and, if it passed a second reading, they had no effective control. Therefore, he considered it best to oppose the Bill, and, having to consider how that could best be done, he had drawn up a form of petition which had been sent for consideration by country members.

The President said he should not make any apology for what he had done; he had done it in the interest of the Society, and should do it again under similar conditions. He agreed with Mr. Sandford that according to the report in the Journal it did appear discourteous on their part not to have communicated again with Sir Michael Hicks-Beach, but under the circumstances it was impossible.

Mr. Schacht asked what was the reason adduced by the Chief Secretary for Ireland why there should be a separate society in Ireland.

Mr. Flux read an extract from the report in the Journal.

Mr. Schacht said that showed that the Irish pharmacists were opposed to a union with that society.

Mr. Frazer said he did not stand on technicalities and therefore should not complain of the informal manner in which the Committee had acted, though he thought it would have been better for them to have signed their individual names instead of using the official paper, and so on. It was very rarely he found himself in the position of supporting any measure brought in by the present Government, but on this occasion he thoroughly went with them—this was an Irish Bill for the Irish people, and he thought they were entitled to get it. Many gentlemen seemed to take it for granted that they were not going to have the same examinations in Ireland as in England, but there was no evidence to that effect.

The President said there was to be only one examination.

Mr. Frazer: So much the better. There was no evidence that they wished to reduce the standard of examination, and from the preamble he gathered that the intention of the Government was to largely increase the number of pharmacists. The statement of one or two of the members was that the pharmaceutical standard must be raised and brought up to the standard of the Major examination; but that was higher than the existing examination for Apothecaries, and therefore they could not suppose the Government was going to meet the present deficiency by heightening the standard. It was said also that no provision was made for meeting the expenses, but the Bill stated that the fees were to be charged for examination. Then it was said that this country would be flooded by Irish chemists; but, as he read the Bill, after they had paid their fees for examination in Ireland, before they could become members of the Pharmaceutical Society, they would have to pay their fees in this country. He believed it would be far better to have separate societies. The only thing in favour of opposing the Bill was in order to suspend it for a year, so that a better measure might be brought forward that would suit both countries.

Mr. Betty could not understand Mr. Frazer's logic, as he said he wished to support the Bill, and yet he should like to see it withdrawn.

Mr. Sandford said, when the Council expressed its willingness to extend the operations of the Society to Ireland, it was under peculiar circumstances. At the time the Pharmacy Act of 1868 was passing through Parliament, there was an effort made by the Irish members to extend the Act to Ireland; but one reason for not doing so was, that they felt it would jeopardize the Bill, and of those who opposed having anything to do with Ireland, their Secretary was then the loudest. Last year another Bill was introduced, which proposed to extend the operation of the Society to Ireland, and Mr. Mackay and himself were called before the Committee to give evidence. They then expressed their willingness to go to Ireland, but by no means their desire to do so, and the evidence they gave to that effect was entirely in accordance with the instructions they had received from the Council. He could not see why they should oppose the Bill *in toto*. They were told by Sir Michael Hicks-Beach that acting on the recommendation of the Select Committee he was determined to have a separate society for Ireland, and seeing that he was so determined he rather thought the best plan would be to try and make this Bill what was wanted. He did not see any advantage in having the same society in two places, and no doubt pecuniarily it would be a loss. Looking at the Medical Act it would be found that the Medical Council had one register of all men qualified in the three kingdoms, but it had the power to send delegates to all examinations, and, before any one was placed on the register, the Medical Council must be satisfied he had passed a sufficient examination. He should decidedly object to the present Bill as it was, but he thought it might be amended, in accordance with the suggestion thrown out by the Chief Secretary, by means of *ad eundem* examinations. There was some little confusion about that term, for, although they knew what an *ad eundem* degree was, they did not know much about an *ad eundem* examination which was a term he had never heard before. But still there was a clear offer to give to English pharmacists the power of establishing examinations for men who came from Ireland and asked to be put on the register. The Bill did not give any ascendancy to the apothecaries. Mr. Flux said if they allowed it to pass the second reading they would have no power over amendments in Committee; but the fact was they must go into Committee before amendments could be introduced. The principle of the Bill was that there should be a separate society for Ireland, and if there were to be reciprocity there must be equal examinations. He knew that Irishmen said their examinations should be as good or better than the English, and that they would have none but pharmaceutical chemists of the highest class. His fear was if there was only one examination and they wanted more chemists, as was stated in the preamble, that examination would degenerate into something not above the English Minor, and he should suggest the adoption of two examinations, as in England. He would also suggest that a power should be given the Society in England over the examinations in Ireland, though he said that very guardedly. The Medical Council now sent visitors to all the examining boards which they recognized, and this Council might do the same thing; there should be a Government assessor, and a member of the Council might attend and satisfy himself that the examinations were thorough and well conducted. The mode of action with regard to the Medical Council was this: if it sent a visitor to an examination, and he thought the examination was not what it should be, he at once reported to the Privy Council, which body, if it thought the complaint well founded, suspended the action of the examining board and no degree could be conferred by it until the matter was put straight. The same thing might be done with regard to the English and Irish examining boards.

Mr. Hampson asked whether that machinery had ever been called into operation.

Mr. Sandford thought most likely it had, though he could not speak positively. At the present time the Medical Council was trying to get one identical examination throughout England, but that would not extend to Scotland or Ireland. He thought they had now an opportunity of settling an Irish question in the way which the Irish people would like, and in a way which would be advantageous to themselves; and he hoped therefore the Council would not oppose the Bill *in toto*. The Council had never given authority for the preparation of a Bill of their own, and he was sorry such an offer had been made to the Irish Secretary.

Mr. Betty thought, instead of criticizing the details of the Bill, the Council would be guided by the general principles which had always been understood to actuate them since first this matter came forward, and which were given expression to before the Select Committee of the House of Commons by Mr. Sandford and Mr. Mackay. Since that time there had been a universal understanding that it was their duty, and at a fit time they would make an effort to carry out what was understood would be done at the time of the passing of the Act of 1868, namely, extend the operation of the Act to Ireland. He was sorry that a gentleman who had so ably stated those views before the Committee should now come and support a Bill utterly opposed to them. Mr. Betty then read extracts from Mr. Sandford's evidence before the Committee to the effect that establishing separate Societies would lead to confusion, that reciprocity would be less desirable than union, and that union would be the best.

Mr. Schacht said they could not have union, it was only on one side. He would propose as an amendment:—

"That the opposition of this Council to the Irish Pharmacy Act be limited to those clauses that convey to pharmacists registered in Ireland the privileges of pharmacists in England.

Mr. Sandford suggested the addition of the words, "unless similar examinations can be established and insured."

Mr. Hampson said that the standard of the examinations could not be guaranteed.

Mr. Schacht said among other reasons for his amendment was the fact that this Society possessed a considerable amount of property, and he did not see why that property was to be shared with a body of men who said they did not want to have anything to do with them. It would be a different thing if Irish pharmacists were desirous of union.

Mr. Atherton said as a local secretary he had received a few days ago the petition to which he was requested by the Committee to obtain signatures against this Pharmacy Bill. He should like to know what would be the position of those like himself in case the motion now before the Council was negatived.

Mr. Hampson said they were only beginning now to discuss and comprehend this question. They opposed the Bill because they believed it to be a mistake, and if the two countries could come together and fully discuss the matter—and they had been in communication with two or three gentlemen representing the Irish Apothecaries who practised pharmacy—he had no doubt they would arrive at a common understanding. There was a deputation, he was informed, now in London from the chemists and druggists of Ireland, who appeared to be totally ignored by the apothecaries, and the object of opposing the Bill was to get it withdrawn, so that all these various parties might be brought together, and, if possible, some common basis arrived at.

Mr. Savage said that at the time it was proposed that the British Pharmaceutical Conference should go to Ireland, they learnt that if they went to the apothecaries the chemists would ignore them, and if they fraternized with the chemists the apothecaries would have nothing to do with them. Therefore, they did not go.

Mr. Williams said he had seen some of the gentlemen from Ireland, and had acquired a great deal of knowledge of Irish pharmacy from them. It appeared there were three parties in Ireland; first, the apothecaries, who had passed an excellent examination, not only in pharmacy, but also in medicine, midwifery, and other subjects. With a few exceptions, these gentlemen were willing to give up the medical part of their diploma, and to confine themselves to pharmacy, and would be glad to be received into the Society. Then there was another body belonging to Apothecaries' Hall, who, he understood, wished to retain their medical as well as their pharmaceutical degree. Lastly came chemists and druggists who were simply sellers of drugs, and he was informed had no knowledge of dispensing or pharmacy in its proper sense. As far as he could gather they would be willing to accept a modified examination for gentlemen of this class. They also thought the only plan was to withdraw the present Bill that there might be time to consider the matter between this time and next year, and bring in another which would be satisfactory to all parties. He might add that the fee for passing the examination at Apothecaries' Hall was fifteen shillings.

Mr. Frazer having seconded the amendment, it was put to the vote and lost, only Mr. Schacht, Mr. Frazer, and Mr. Sandford voting in favour of it.

The original motion was then put and carried, the same three gentlemen voting against it.

Mr. Betty moved :—

"That a deputation, consisting of the president, vice-president, the treasurer, and Messrs. Hampson and Betty wait on the Chief Secretary for Ireland as soon as an appointment could be made."

He took it that these gentlemen would represent to the Chief Secretary the views which had been expressed that morning and, as he understood, they would oppose the Bill as it was *in toto*, but if it were to be carried at all that it should be a purely Irish Bill, and not attempt anything in the way of reciprocity with England.

After some discussion the resolution was carried,

Mr. Hampson then moved :—

"That the petition from this Council, which has just been considered, be sealed and presented to Parliament forthwith."

At the request of Mr. Hampson, the Solicitor read the Petition as follows :—

"To the Honorable The Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled—

"The humble petition of the Pharmaceutical Society of Great Britain

"Sheweth,—That your petitioners have considered 'A Bill to constitute a Pharmaceutical Society, and to regulate the qualifications of Pharmaceutical Chemists in Ireland, and to establish certain relations between the Pharmaceutical Society of Great Britain and Ireland' now before your Honorable House.

"That your petitioners regard the proposals of the said Bill as likely to prove injurious to the interests of Great Britain and not likely to advance the interests of Ireland.

"That your petitioners regard as desirable in the interests of the United Kingdom the extension to the whole of the kingdom of the laws which now within Great Britain regulate the qualifications of Pharmaceutical Chemists and Chemists and Druggists, and also the Sale of Poisons.

"Your petitioners therefore pray that the said Bill now in your Honorable House may not be passed, and that a Bill may be passed which shall extend to the whole kingdom the laws which now within Great Britain regulate the qualifications of Pharmaceutical Chemists and also the Sale of Poisons.

"And your petitioners will ever pray, &c."

The Vice-President seconded the motion.

Mr. Schacht moved as an amendment :—

"That no petition against the Irish Pharmacy Bill be presented by this Council."

He said that his ground of objection was that it did not simply content itself with opposing the present Bill, but went on to advocate something else which he objected to.

Mr. Frazer seconded the amendment, but on a vote being taken, it was negatived. The original motion was then put and carried.

The seal of the Society was then affixed to the Petition.

Drugging of Animals Bill.

Mr. Sandford said there was another Bill just introduced into the House of Commons, the second reading of which stood for the next evening, its object being to make it a punishable offence to administer certain drugs to horses and other animals. Not only so but it re-enacted a great part of the Pharmacy Act, 1868, and subjected the poisons included in Part 2, of Schedule A, together with some substances not at present included in the schedule at all, to restrictions as to sale applying at present only to poisons in Part 1 of the Schedule.

The President thought the consideration of the Bill should be referred to the Law and Parliamentary Committee.

The Vice-President said the introducer of this Bill had clearly gone a great deal further than he intended, because some of the articles enumerated were frequently given by grooms, or those having the care of horses, and were of the greatest assistance, and often saved the life of a valuable animal.

The Solicitor said, as this was a matter which related to horses, it would be pretty sure to attract attention in the House of Commons, and it seemed too absurd to have any chance of passing.

Mr. Baynes thought they ought to lose no time in opposing it, and should not assume that its absurdity would be an obstacle.

It was then resolved :—

"That the Law and Parliamentary Committee be requested to take such steps as they may deem necessary to oppose the Drugging of Animals Bill."

Benevolent Fund.

Several members of the Council, acting as a Benevolent Fund Committee, had held a meeting to consider applications for relief, and recommended the following grants :—

£20 to be placed in the hands of Mr. Owen for the purpose of assisting to put into the London Orphan Asylum at Watford, the child of a widow, whose case has been reported before.

£10, being a second grant, to the widow of a chemist and druggist.

£7 10*s.* towards enabling a former member to emigrate.

Several other applications had been considered and deferred for further consideration. The Committee also reported that there were at present, sixteen annuitants, seven men, and nine widows; that there were four candidates who were unsuccessful at the last election, since when two more names had been added to the list of approved annuitants. They recommended the Council to elect four annuitants in October next.

Mr. Brown moved, and Mr. Robbins seconded, that the report and recommendations of the gentlemen acting as the Benevolent Fund Committee be received and adopted, which was carried unanimously.

Election of Four Annuitants.

It was moved by Mr. Brown, seconded by Mr. Robbins, and resolved:—

"That it is expedient financially to elect pensioners on the Benevolent Fund in October next, and that four pensioners be elected accordingly.

The Secretary said he wished the Council would take into consideration the advisability of giving a greater interest in the way of votes to those who subscribed to the Benevolent Fund.

Preliminary Examination. — One certificate of the College of Preceptors was received in lieu of the Society's Examination.

The Glasgow Memorial.

Mr. Frazer moved the resolutions of which he had given notice in reference to the Glasgow memorial as follows:—

"That after the 1st January, 1876, candidates for the various examinations of the Society shall continue to have the option of entering on these on the present footing; or, on that of foregoing their right, in case of failure, to receive back any part of the fee for the respective examinations; in the latter case those students who adopt it shall have two additional opportunities of passing for the fee so retained.

"Further:—That students who pass with credit in two subjects in the Preliminary and Minor Examinations, and in one subject in the Major, but who fail to pass in all the subjects of each examination, shall be credited with the subjects in which they do pass, and so be, on their second appearance, examined only upon those subjects in which they failed to pass on their first examination.

"Again:—That this Council, in regard to the views advocated in the Glasgow memorial, recommend that in future nominations, the Edinburgh Council in sending up names of gentlemen to constitute the Scotch Board of Examiners should, as far as possible, make the selection from a larger area than they have hitherto been in the habit of doing.

"And finally:—This Council also recommend that the Council of the North British Branch take into consideration, in deference to the expressed wish of their Glasgow brethren, the desirability of holding at least occasional examinations in Glasgow, provided this can be done without incurring an undue expenditure of the funds of the Society."

He said it must seem strange that he should bring forward this matter, about which so much had been said, in the absence of Mr. Mackay, but he did so with the full concurrence of that gentleman, not in the terms of the resolution, but in its being brought forward now instead of deferring it until July, as he would willingly have done. He was happy to say that the personal matter was now entirely at an end between Glasgow and Edinburgh, the alleged want of courtesy having been entirely explained, the Edinburgh gentlemen being quite satisfied that no offence to them was intended. After referring to a personal matter affecting Mr. Fairlie, Mr. Frazer said he had not seen any of his Glasgow friends since the meeting with the exception of two, neither of whom were anxious that he should bring the matter forward, and one was in fact opposed to it, but as he had undertaken to bring the memorial before the Council, he did not like to interpose his individual opinion, and though he did not agree in all their views, he thought it only right to submit them in the form of the resolutions. After stating some additional facts to strengthen the position he had taken on a former occasion, that there was a great difficulty in obtaining apprentices and assistants, he read a letter from Mr. Currie supporting the views of the memorialists, and especially alleging that a slight alteration in the Minor examination would be a great relief to the candidates, and reduce the number of failures without impairing its efficiency. In conclusion he repeated that he was not to be understood as individually supporting the whole of the memorial or the resolutions in their entirety—indeed, he was opposed to the two last, and he yielded to no man in his appreciation of the respect for the members of the Examining Board in Edinburgh, with all of whom he was personally acquainted.

Mr. Williams seconded the motion *pro formâ* in order that it might be fairly discussed.

Mr. Cracknell said it appeared to be the opinion of Mr. Frazer that it was entirely owing to the examinations that there was so much difficulty in obtaining apprentices and assistants, but this he could not admit to be the case. He had made inquiries on this subject and found that throughout the provinces other trades and businesses found a like difficulty, much more so than formerly. He believed the true explanation to be that there is a growing disinclination amongst the educated classes to engage in retail business of any kind, whilst the market is flooded with clerks of all kinds at almost any remuneration. It was possible that the examinations might to some extent restrict the number of those engaged in their trade, but if this check did not exist many would enter it who were not educated in the proper manner. The alterations suggested in the first paragraph would give rise, in his opinion, to great confusion, and would not be at all desirable. It had been urged that, if candidates were allowed to forfeit their fees in the event of ultimate failure, the number of unprepared candidates presenting themselves for examination would be diminished; but he did not think this would be the case—at any rate, it would be only so in regard to the last examination. In regard to the second paragraph, he must, as a late examiner, say that he considered what was proposed very undesirable, and not only so, but impossible of adoption, because he knew it was adverse to the views of every member of the Board of Examiners. This subject had been thoroughly ventilated and discussed in both London and Edinburgh, and the system now proposed in the motion was condemned, he believed, without a dissentient voice on either Board. The Minor examination was intended to denote the competency of the candidate to carry on the business of a chemist and druggist, but it must do so as an entirety, and not deal with mere portions. What would be thought of a man who passed on the first occasion in two subdivisions of the examination, in two more after an interval of three months, in two more after another interval, and the remaining two at a final examination? The examination was really one entire whole, not a compound of various sections, and was only sub-divided for the convenience of the examiners. The object, he supposed, was to make the matter easier for candidates; but the fact was, it would only open the door to cram, a thing which he believed they would all deprecate. The third paragraph he understood was not really pressed, and he was happy to find that Mr. Frazer disclaimed any intention to impugn the action of the Scotch Board of Examiners. From what he had seen of those gentlemen he could safely say that gentlemen possessing higher integrity, or who acted more with a desire to do their best for the Society and for the candidates he had never met.

Mr. Hampson thought there was some inconsistency in the propositions now put forward. It was alleged that the standard of the examinations deterred men from entering the trade, and, to be consistent, their Scotch friends should commence an agitation to lower the standard, but this they did not propose to do.

The Vice-President said he could not give a silent vote on this question, especially having recently had the pleasure of visiting Edinburgh and Glasgow with his friends, Mr. Cracknell and Mr. Carteighe. A better set of pharmacists he would not wish to find than the gentlemen he met in Glasgow, and he could only regret that this little difference between them and their friends in Edinburgh had not cropped up then, as it might very probably have been calmly discussed and settled, and would then never have been heard of in London at all. He thought nothing could be more suicidal than to alter the examinations at the present moment; they had been altered recently, and had not yet had a fair trial, so that it would be most unwise to make any further change at present. With regard to the last paragraph, it was not a question of funds; they had authority to hold examinations in Edinburgh, in Glasgow, *or* elsewhere in Scotland; but they had no authority to hold them in more places than one; the word was "or," not "and," and if they were to go from Edinburgh at all, Aberdeen would have quite as good a claim as Glasgow. But then Manchester, Birmingham, Bristol, and other large manufacturing centres would have equal claims. On these grounds, without any disrespect to their Glasgow friends he thought it unwise to attempt the holding of examinations anywhere except at two metropolitan centres.

Mr. Baynes had sympathized to some extent with Mr. Frazer's views on the question of the examination, but only to the extent that he thought they had raised the standard rather too soon, and he should now firmly resist any departure from the present regulations. There was an idea afloat that it was intended in a few years still further to raise the standard of the examinations, and it was therefore of the utmost importance that it should be clearly understood that no change at all would be made.

Mr. Betty thought there was very little to be said in favour of the motion after the lucid exposition of the question which had been given by Mr. Cracknell, and he should hope Mr. Frazer would be content with the ventilation of the subject and not press the motion. The question of dividing examinations and passing in part at a time had been under discussion for the last ten years and the great majority of opinion was dead against it. The whole of the knowledge was required at one time not piecemeal.

Mr. Williams said that financially the examinations were not profitable, and therefore it was a very serious matter to sacrifice any portion of what was now received. It was a thing he could not agree to.

The Secretary read a statement he had prepared of the receipts and expenses connected with the Minor and Major examinations, showing that at some meetings of the Board there was a loss, and never more than a small surplus, without taking any account of clerks and establishment charges, which would, if added, show that a constant loss was incurred.

Mr. Frazer in reply said he contended that the examinations were a considerable source of gain to the Society; he estimated it, in fact, at upwards of £1500 in the year 1873. With regard to the question of partial examination when the candidate had already passed in certain subjects he knew positively that it had the support of almost the whole of the Edinburgh examiners, though they did not attempt to take action in the matter, knowing it was opposed to the views of the London Board. He could not discuss the merits of the question himself, not being prepared to do so, but he knew those were the views of the gentlemen who had considered it. Some gentlemen spoke as if he had advocated a lowering of the standard, but he had done nothing of the sort, though he had opposed the last change, thinking it a great mistake. The case of Ireland showed clearly what was the effect of having too stringent an examination; it simply drove men into the ranks of the medical profession. He quite agreed with Mr. Cracknell that there was a like difficulty in many other trades, but that was a reason why they should not throw more obstacles in the way of young men than were absolutely necessary.

Mr. Baynes suggested that the motion should be withdrawn, but

Mr. Frazer said he should prefer to take a vote upon it. It was accordingly put, but received no support beyond that of the mover himself.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' SOCIETY OF IRELAND.

The session of this Society came to a termination on Friday evening, the 30th ult. The classes which have been conducted by Professor Titchborne and Dr. Frazer have throughout been remarkably well attended. At the conclusion of the course the Society offered a prize of £2 2*s*. for competition in the chemistry class, to which Professor Titchborne generously added a second prize of a guinea. Several of the students competed for the prizes. The following were the successful candidates:—First prize, William Furlong, apprentice to Mr. Holmes, Upper Baggot Street; second prize, S. D. Chandlee, apprentice to the Apothecaries' Hall of Ireland.

Professor Titchborne reported as follows:—"The answering was generally very good, and five of the candidates scored very high."

A cordial vote of thanks was voted to Mr. Hayes, Hon. Sec., for his untiring zeal in the interests of the Society.

The following gentlemen have been appointed as Subcommittee to watch the interests of the Society in the passing of the Irish Pharmacy Bill, at present before Parliament:—Mr. E. M. Hodgson, President; Mr. W. Hayes, Hon. Sec., and Messrs. William Allen, J. T. Holmes, and Robert Simpson. The Bill is generally approved by the Society with some exceptions. So far as reciprocity with the Pharmaceutical Society is concerned the Society is quite indifferent. The opinion of the Society is that it would be well to continue two classes, viz., chemists and druggists and pharmaceutical chemists.

The Society is also anxious about the constitution of the proposed first Council and is of opinion that the members of the Society should be fairly represented there.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Irish Pharmacy Bill.

The second reading of this Bill, which had been set down for Monday last, was postponed until Thursday the 3rd inst. On Thursday, on the motion of Sir Henry Selwyn-Ibbetson, it was again postponed until Monday next, the 7th of June.

Mr. Salt will then move that the Bill be read a second time that day three months.

During the present week, petitions against the Bill from the following places have been presented :—

Abingdon ....Mr. John Creemer Clarke.
Ashby-de-la-Zouch...Lord John Manners.
Ashton-under-Lyne Mr. Thomas W. Mellor.

DRUGGING OF ANIMALS BILL.

The following is the text of the Bill to make the administration of Poisonous Drugs and compounds to Horses and other Animals a punishable offence, which has been read a first time in the House of Commons :—

Whereas it is expedient to make provision for putting an end to the practice of administering poisonous drugs and other compounds to horses and other animals by disqualified persons, and without the knowledge and consent of the owners of such horses and animals :

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows :—

1. From and after the *passing of this Act* if any person other than a member of the Royal College of Veterinary Surgeons of Great Britain, or any person acting under his direction, shall give any horse or other animal any one or more of the several articles named or described either in Part I. or Part II. of the Schedule A. to this Act without the consent of the owner of such horse or animal, such person shall be deemed guilty of a misdemeanor, and shall on conviction thereof be liable for each offence to a penalty or sum not exceeding *ten pounds*, or to be sentenced to be imprisoned, with or without hard labour, for any term not exceeding *three calendar months ;* but nothing in this Act contained shall exempt any person from any heavier punishment to which he might be liable under any other Act, provided that no person shall be punished twice for the same offence.

2. The several articles named or described in Part II. of the Schedule A. to this Act shall be deemed to be poison within the meaning of this Act.

3. It shall be unlawful to sell any poison, either by wholesale or by retail, unless the box, bottle, vessel,

wrapper or cover in which such poison is contained be distinctly labelled with the name of the article and the word poison, and with the name and address of the seller of the poison, and it shall be unlawful to sell any poison to any person unknown to the seller, unless introduced by some person known to the seller; and on every sale of any such article the seller shall, before delivery, make or cause to be made an entry in a book to be kept for that purpose, stating, in the form set forth in Schedule B. to this Act, the date of the sale, the name and address of the purchaser, the name and quantity of the articles sold, and the purpose for which it is stated by the purchaser to be required, to which entry the signature of the purchaser and of the person, if any, who introduced him shall be affixed; and any person selling poison otherwise than is herein provided shall, upon a summary conviction before two justices of the peace in England, be liable to a penalty not exceeding *five pounds* for the first offence, and to a penalty not exceeding *ten pounds* for the second or any subsequent offence, and for the purposes of this section the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller; but the provisions of this section shall not apply to articles to be exported from Great Britain by wholesale dealers, nor to sales by wholesale to retail dealers in the ordinary course of wholesale dealing, nor shall any of the provisions of this section apply to any medicine supplied by a legally qualified apothecary to his patient, nor apply to any article when forming part of the ingredients of any medicine dispensed by a person registered under the Pharmacy Act, 1868: Provided such medicine be labelled in the manner aforesaid, with the name and address of the seller, and the ingredients thereof, be entered with the name of the person to whom it is sold or delivered in a book to be kept by the seller for that purpose; and nothing in this Act contained shall repeal or affect any of the provisions of an Act of the Session holden in the fourteenth and fifteenth years of the reign of Her present Majesty, intituled "An Act to regulate the sale of arsenic."

4. Penalties recoverable under this Act may be recovered in a summary way before any two or more justices of the peace in petty sessions assembled, and according to the provisions of any Act regulating the powers and duties of justices of the peace; and one-third of every sum of money recovered as a penalty under this Act shall be paid to the person who shall be the means of bringing to justice any person committing any offence against any of the provisions of this Act.

5. This Act shall not apply to Scotland or Ireland.

6. This Act may be cited as "The Drugging of Animals Act, 1875."

SCHEDULES.

Schedule (A.)

PART I.

Arsenic and its preparations.
Prussic acid.
Cyanides of potassium and all metallic cyanides.
Strychnine and all poisonous vegetable alkaloids, and their salts.
Aconite and its preparations.
Emetic tartar.
Corrosive sublimate.
Cantharides.
Savin and its oil.
Ergot of rye and its preparations.
Oxalic acid.
Chloroform.
Belladonna and its preparations.
Essential oil of almonds, unless deprived of its prussic acid.
Opium, and all preparations of opium or of poppies.

PART II.

Sulphuric acid	or oil of vitriol.
Nitric acid	or aqua fortis.
Hydrochloric acid	or spirits of salts.
Muriatic antimony	or butter of antimony.
Sulphate of iron	or green vitriol.
Sulphate of copper	or blue vitriol.
Sulphate of zinc	or white vitriol.

Schedule (B.)

Date.	Name of Purchaser.	Name and Quantity of Poison sold.	Purpose for which it is required.	Signature of Purchaser.	Signature of Person introducing Purchaser.

Alleged Adulteration of Vinegar.

At the Stone Police Court the adjourned proceedings against Mr. Thomas Slater, chemist and grocer, Stone,* taken at the instance of Major Knight, inspector under the Adulteration Act, for selling vinegar alleged to be adulterated, were resumed after an interval of two months. It will be remembered that the vinegar was purchased at the defendant's shop by Major Knight's assistant, and submitted to Mr. Scott, the county analyst, who certified that the vinegar was adulterated with lead so as to be injurious to health, and also with sulphuric acid. The result of the analysis was not satisfactory to Messrs. Hill and Evans, of Worcester, the manufacturers of the vinegar, and, having obtained the assent of the Bench, they determined that further analyses should be made. Accordingly the portion of vinegar remaining after Mr. Scott's analysis was sent to Dr. Thudichum, of London, and two independent samples of the same vinegar were forwarded by Mr. Slater to Dr. Letheby and Dr. Voelcker. At the last hearing of the case the last-mentioned chemists were present, and stated that the vinegar was perfectly free from lead, and from the noxious element of free sulphuric acid. Of combined sulphuric acid they found 112 grains per gallon, but that was a constituent of the water from which the vinegar was made, and was not at all injurious to health. They pointed out that unless the vinegar was tested with the utmost care the one element, which was perfectly innoxious, might be taken for the other and dangerous ingredient. Dr. Thudichum, on the other hand, though he was not then present, sent a certificate stating that the vinegar which he had received was adulterated with sulphuric acid so as to be injurious to health, but he made no mention of lead, one of the adulterants which Mr. Scott had found. Under all these conflicting circumstances the case was adjourned in order that Dr. Thudichum and Mr. Scott should be present, and have an opportunity of upholding the conclusions to which they had come. At the last hearing, as on the former occasion, Mr. C. Fulford, barrister, instructed from the office of Messrs. Hand, Blakiston, and Everett, appeared for the prosecution; and Mr. Underhill, barrister, instructed by Mr. Southall, of Worcester, for the defence. Mr. Fulford having opened the case, Mr. Scott was called, and stated that the results of his analysis were contained in the certificate which had already been before the Court. He found the vinegar to contain 119 grains to the gallon of monohydrated sulphuric acid, and containing that amount of sulphuric acid he thought it was unfit for human consumption. The witness was subjected to a long and searching cross-examination. By the first test he used what he found might either have been free or combined sulphuric acid, and in his expe-

* See before, p. 842.

rience he had known water so strongly impregnated with sulphates as to produce combined sulphuric acid. Whether that acid would be injurious to health or not would depend upon quantity. The specific gravity of the vinegar he analysed was 1·0168. Re-examined, witness said that some of the sulphuric acid was undoubtedly free to the extent of about thirty-six grains to the gallon. It appeared that Mr. Scott had sent a portion of the vinegar to Mr. Jones, the county analyst, asking him to test for lead, and Mr. Jones was called to state the result of his analysis. He stated that he found lead unmistakeably present, but the quantity of vinegar which he had to analyse was so small that he could not tell to what extent, though he believed there was quite half a grain to the gallon. Dr. Thudichum deposed that he had been employed by the Privy Council in analytical matters for the last eleven years, and had had a large experience in the analysis of wine and vinegar. He analysed the vinegar sent to him through Mr. Middleton, and found it to contain 111 grains of sulphuric acid to the gallon. He made no test to accertain whether the acid was in a free or combined state, but even if the acid was produced by sulphates in the water its presence to the extent of 111 grains would render that water unfit for ordinary purposes of consumption, and in his opinion also unfit to be used in the manufacture of any articles of food. He considered that anything above thirty-six grains of sulphates per gallon would be an adulteration, and the inference to be drawn was that the vinegar made from it would be injurious. This was the case for the prosecution, and Mr. Underhill addressed the Court for the defence. He referred to the celebrity which his clients' vinegar had attained, and to different occasions on which its purity had been called in question, the result always being that its character as a condiment was vindicated. He pointed particularly to the fact that Dr. Thudichum had not made the test spoken of by Dr. Letheby in order to detect the presence of free sulphuric acid, and, arguing that there was nothing in Dr. Thudichum's evidence to show that the sulphates were not contained in the water from which the vinegar was made, he quoted in opposition to Dr. Thudichum's statement that these sulphates were injurious, the opinions of several chemists of great reputation who had analysed the water at Messrs. Hill and Evans' factory, and had certified to its being in every respect eminently suitable for the purposes for which it was used. The fact was, the learned counsel said, like the Burton ales, the quality of the vinegar was enhanced by the character of the water. The Bench were then asked to consider whether the defendant, Mr. Slater, a respectable man, was likely to have tampered in any way with the vinegar, and the fact was pointed out that the specific gravity of the vinegar examined by Mr. Scott was the same as that sent by Mr. Slater himself to Dr. Letheby, which was some evidence that the vinegars were one and the same. Mr. E. H. Hill, a member of the firm of Messrs. Hill and Evans, was then called for the defence, and gave evidence bearing upon the manufacture of the vinegar. Dr. Letheby deposed that the specific gravity he found in the vinegar sent to him by Mr. Slater was exactly the same as that found by Mr. Scott—a fact which would point to the vinegars being the same. There was nothing in it which was in any way injurious to health or in any way detracted from the value of the vinegar. Sherry contained three or four times as much combined sulphate as the vinegar, and there was no evidence that the former article was injurious when taken in moderation. The water at Messrs. Hill and Evans' factory was one of the finest waters that could be used for the purpose. The Bench, after a short consultation with the clerk, said there was so much difference of opinion among the chemists that they had decided to dismiss the case, and they might say that they believed there was no imputation whatever upon the character of Hill and Evans' vinegar. They also considered that Mr. Scott, the county analyst, had done his duty in the case. Mr. Fulford asked the Bench to grant a case upon a point of law which he had raised during the hearing—viz., whether, assuming Dr. Letheby's statement to be correct, that the water from which the vinegar was made contained 112 grains of combined sulphuric acid, and was totally unfit for ordinary purposes of consumption, such water did not introduce into an article manufactured from it ingredients which were as much an adulteration as if the adulterating matter had been added. The point was important for this reason—that the defence in the present case having succeeded, what protection would there be, in the case of matters which were injurious, if it could be said that these matters were natural to the water? The Bench held that there was nothing to grant a case upon, as they had dismissed the summons upon the grounds of discrepancies in the scientific evidence.—*Grocer.*

Correspondence.

Official *versus* Officinal.

Sir,—Having for a long time been engaged upon a new etymological dictionary of the English language, perhaps I may be permitted to offer an opinion on the meaning of the terms "official," and "officinal." Officinal is certainly derived from the Latin "officina," which means, primarily, a workshop, a manufactory; secondarily, a shop or place where anything is sold. In pharmacy it has long been the term applied to such medicines or drugs, simple or compounded, as were required by the College of Physicians to be kept in the apothecaries' shops ready for use, or to be mixed up in extemporaneous prescriptions, so that the idea raised in the mind by the use of the word officinal, was "such as you will find at the shop." "Official" (Latin "officialis") means now an officer or an authorized and appointed person for the performance of official duties (*vide* Cicero, *De Officiis*). Magistrates, judges, and their decisions, writings, judgments, orders, etc., are said to be official as pertaining to an officer. This word "officialis," was certainly first introduced at the end of the thirteenth century, and was then limited to the person who acted as the bishop's deputy, or to an ecclesiastical judge appointed by him—but soon became extended. Now, as to the paper of Dr. Miller, I think Mr. Ince writes with great knowledge of the subject, but I venture, as an old Cambridge scholar, to observe that many learned philologists believe both the words officinal and official to spring from the same radix, viz., from *officio*, which, in early Roman literature, had the same meaning as efficio. No doubt some believe "officina," to be abbreviated from *opificina* which, like *opifex*, of course came from "opus" and "facio;" but *officio* comes also from *ob-facio*, as a radix, so that philologically, Dr. Miller may be right, though not having heard or read his paper, I cannot judge. But he is certainly wrong in the recognized meaning and distinct meaning of the two terms.

John Fredk. Stanford, M.A., F.R.S.

The Major Qualification.

Sir,—In last week's "correspondence" we were told that "it is very difficult to make out a good case when recommending young men to 'continue their onward course until they have attained the highest rank.'"

The writer mainly agrees with "Urtica" that he is right if such arguments as he names are alone to be taken into consideration. But as "a young man" studying after the attainment of this "highest rank," kindly allow me for one to say that the case the present writer makes out to himself is not exactly the honour of attaching to his name the distinctive letters "P.S." or "M.P.S.," or—as a sure guarantee to the public of business ability—the attractive title of "Pharmaceutical Chemist," though this, as years roll on, will be no mean advantage; understood in its fulness it will then be a sign of better qualification, instead of—as is too frequently the case now with the public—a name or *nom de plume*. The case the writer makes out to himself is rather something beyond or above these considerations—the pleasure, satisfaction, and benefit, or whatever one likes to call it, derived from the study of science and the practice of art, demanded by the "Major." The accumulation of such scientific and general knowledge is always a pleasing task to every genuine student (one who studies with other objects than "cramming up" for an examination) independently of honourable titles gained thereby. Surely if "knowledge is power"—as daily experience proves it to be—then gaining of knowledge is a reward in itself and in the end cannot but yield good interest. This at least is the experience of the writer who has good reasons for believing that it is the same of many others, and probably those who stop short of the highest grade are about the only exceptions. The notion about studying merely with the object of passing an examination for the sake of the title it brings (though not to be despised)—as though the gain of knowledge was of no subsequent use—without any higher aim, is erroneous in principle and the sooner it is eradicated from our minds the better will it be for the best interests of all concerned.

But a young man not possessing this higher title, only studying for it alone and unaided, save by books and his own experience, must not say too much or he may remind one of the maid who "counted her chickens before they were hatched." Be this as it may, certain he is that he will have derived great and lasting benefit from the study after the required knowledge,—found it to be a reward in itself,—the possession of which he regards as of greater value than the mere honour of signing himself "P.S." or "M.P.S." These titles are very good, but knowledge gained is better.

T. T.

Trowbridge, May 29, 1875.

Dispensing Charges.

Sir,—"A North Countryman" calls attention to the case of a physician who recommends his patients to a chemist who charges half price for dispensing his prescriptions. We are not altogether ignorant of such devices in the south. I live in a fashionable town where I am informed such prescriptions as the following are dispensed for a shilling:—

Potassæ Bicarbonatis	ʒij.
Tincturæ Cinchonæ Compositæ	℥ij.
Infusi Calumbæ	℥vj.
	M.

A young medical man, of undoubted ability, who seeks to establish himself here, and wisely resolves not to dispense his own medicines, has more than once applied to me to charge his patients at a reduced rate, that they may be (so he states) the better able to pay his fees. Such a course is impracticable. But having more mouths to feed daily than one figure can express, I have endeavoured to find a means of meeting the doctor's difficulty without compromising any principles. I have offered to dispense for him at a fair charge to the profession; and as he seems unwilling to incur responsibility I have proposed to transact his pecuniary business with his patients, by his making a gross charge for medicine and advice, which sum should be paid to me on his account, with a distinct understanding on the part of the patient of the nature of the transaction. Or I have consented to adopt any superior plan, provided always that there should be no secret understandings. It is evident from his repeated applications that he is at least not unwilling that I should dispense for him; but for a long time I have not even seen him. Occasionally his prescriptions turn up, and if the last I received (yesterday) is a sample, the chemist who enjoys his patronage has not much to be thankful for. It is as follows,—I give it literally—

"℞ Tinct. Sulph. . . . . . . gr. xvj.
Tinct. Lavand. Co. . . . ♏ xij.

ft. Pulvis (!) Say to be put to half a pint of rain water for a lotion." I should infinitely prefer that no arrangements at all should be made between chemists and prescribers, but if they are made they should be "understanded of the people." The remedy for such evils is genuine co-operation; but that virtue seems to have been monopolized by civil and uncivil public servants and working men.

Henricus.

Pharmaceutical Titles.

Sir,—Would you kindly allow me through your columns to seek information as to what is the proper contraction for "pharmaceutical chemist" when used as a qualification?

I observe on the voting papers issued for the election of members of Council "P. C." is used to distinguish this class, and your correspondent "Urtica," in last week's Journal, possibly following what ought to be an authority, likewise makes use of these letters; but, sir, I have understood that "P. C." has meant "Privy Councillor" since before the Pharmaceutical Society had existence. Again, numerous correspondents use "Ph. C.," and I am not aware that this contraction has had other meaning attached to it than that under consideration; but I seek information on this point, since I have seen "Ph. Ch." used in an inscription on a piece of plate presented to a well-known member of our Society by other members. If "Ph. C." has not been taken up by any other college or society, why add the superfluous "h?" and since "P. C." has been appropriated by a select and brilliant few, why seek to disturb their property?

Though, alas! the title "pharmaceutical chemist" in past times has failed to command the respect we could desire, there is now a brighter day dawning when the title will be coveted and used with pride; and it is fit that the contraction, which is sure to be used most frequently, should be decided on and adhered to on all occasions.

Perhaps some member learned in such matters will have the goodness to speak authoritatively on the subject.

C. E. W.—We think it would be unsafe to use such a label without affixing a stamp or previously consulting the inland revenue authorities.

"*Dentist, Middlesex.*"—We are not aware that any such regulation is coming into force. Apply at the College of Surgeons.

J. M. Fairlie.—In reply to your communication stating that you have no objection to our consulting the Honorary Secretary of the North British Branch respecting the publication of the 15th ult., we have to state that you appear to have misunderstood the suggestion we put forward last week. We have no intention of consulting that official on the subject, though our opinion is that the publication of your letter at least requires his concurrence, and that it should have been in the first place addressed to him rather than to the Journal.

"*A Major Student.*"—(1) The formula may be so represented. (2) Equation (*a*) represents the reaction.

T. Lunn.—The crystals consist almost entirely of chloride of potassium.

NOTICE.—Considerable inconvenience and disappointment are frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ*. A compliance with the explicit instructions published weekly over our Editorial columns will prevent delay, and the consequent annoyance.

Communications, Letters, etc., have been received from Messrs. Swinn, Wills, Robson, D. Howard, Nichols, Garside, Druce, Reynolds, "Pharmacist," "A Poor Chemist," "Honor," J. B. S., W. H.

NOTES ON BRAZILIAN DRUGS.

BY E. M. HOLMES,
Curator of the Museum of the Pharmaceutical Society.

(*Concluded from page* 905.)

Erva do Rato.—This drug consists of leaves, but they arrived in so injured a state, that it is not possible to describe them. The leaves and fruit, in the state of powder, are used in Brazil to poison rats and mice. Dr. Barnsley attributes the drug to *Palicurea Marcgravii*, St. Hil. He states that it is a most deadly poison, and that a great number of mules and sheep are annually killed by eating it, death following in 5 to 8 hours after ingestion. According to Martius both this species and *P. nicotianæfolia* are powerful poisons, but the latter in small doses is used in veterinary practice for dysuria in horses and mules, while two other species, *P. officinalis*, Mart., and *P. densiflora*, Mart., possess diuretic properties, and are used in syphilis, rheumatism, etc. He states that their action resembles that of Digitalis in its effect upon the heart. There can be no doubt that the plants of this genus possess powerful properties, and are certainly worthy of scientific investigation.

Fruita de Gentio.—This drug consists of small baccate fruits of a yellowish colour, about the size of a filbert, and containing from 4 to 6 flat seeds immersed in dried pulp. Each seed is about half-an-inch in diameter, and one-eighth of an inch in thickness; the seed is notched at the base, with the micropyle forming a little projection in the notch; the nucleus is oval, and occupies only a small portion in the centre of the seed; the circumference of the seed, to the depth of one-eighth of an inch, consists of a hollow raised rim, so that the portion of the seed containing the nucleus is oval and depressed. The nucleus is exalbuminous, and consists of two flat, oily cotyledons, with the radicle near the hilum. The cotyledons are tasteless, but the pulp in which the seeds are immersed is extremely bitter. According to Dr. Barnsley, the fruit and seeds are used in the form of powder and tincture as a drastic purge, and are a favourite remedy with the lower class of Brazilians. He does not know the plant yielding the drug, but the characters above described show that the seeds probably belong to the Cucurbitaceæ.

Japicanga.—This is the rootstock or "chump" of some species of sarsaparilla. It has but a small portion of rootlets attached; these have a hard woody meditullium, a thin dark brown cortical portion, and are smooth externally. It has no distinct taste. According to Dr. Barnsley it is used in the province of Rio as a substitute for the sarsaparilla of the Amazons. He refers the drug to *Smilax glauca*, Mart. The name Japicanga, which is variously spelt Japecanga, Jupicanga, Inhapecanga, is a generic term for any kind of sarsaparilla in Brazil.

Jarrinha.—This drug occurs in slices about half-an-inch thick, and two inches in diameter; the meditullium is about one inch in diameter, and has a radiate appearance owing to the presence of a number of very narrow yellowish woody wedges which have thick white medullary rays between them, and the woody wedges when examined with a lens are seen to be full of large porous vessels. Outside of the meditullium is a horny portion a quarter-of-an-inch in thickness, and outside this layer is a soft corky layer of the same thickness. It has the peculiar camphoraceous odour common to several nearly allied species of *Aristolochia*. The taste is slightly acrid but not bitter. It is certainly the root of a species of *Aristolochia* and is attributed by Dr. Barnsley to *A. cymbifera*, Gom. (Mart.?). He states that the root is very useful for colicky pains, and that it is used as a tonic, and for gangrene. By the natives it is esteemed a sure remedy for snake-bites. It is very abundant in every part of Rio and S. Paulo. Several species of *Aristolochia* are used under the name of Sipo de Jarrinha or de Mil-Homens. According to Martius they are used for the same complaints for which valerian is used in this country, and are considered superior to *Aristolochia serpentaria*.

Pipi.—This drug is a long-branched woody root, about eighteen inches long, half-an-inch in thickness in the upper part, and tapering downwards to one-eighth of an inch. The root is pale brown and smooth externally; a transverse section shows a large white woody meditullium, filled with minute pores, but with the medullary rays indistinct, the cortical portion very thin, of a brown colour, and readily scaling off when the root is bent. The taste is slightly bitter, and causes a sensation of tingling when chewed.

Dr. Barnsley states that a tincture of the root forms an admirable remedy for chronic rheumatism, lumbago, and muscular paralysis, and that it is much used in the province of Rio by country physicians. Martius refers the plant yielding the root to *Petiveria tetrandra*, Gom. The leaf which accompanied the root is, however, not that of *Petiveria tetrandra*, Gom., but that of some twining plant with opposite leaves—probably belonging to the Malphigiaceæ.

Quina quassia.—This drug is a bark of a greyish colour externally, with a number of short pale brown transverse scars. The epidermis is very thin, and can be readily scratched off by the finger nail, leaving the white portion underneath exposed. The bark is fibrous, but is nevertheless very tough, and breaks with a rather short fracture. When cut transversely with a sharp knife the layer just inside the epidermis (mesophlœum) is seen to be irregular in outline and much whiter than the inner portion. The taste is intensely bitter.

Dr. Barnsley does not know to what order the plant yielding it belongs, but he having sent a portion of the plant with the barks, I have been enabled (with Professor Oliver's kind assistance) to identify it as the *Picrasma Velosii*, Pl., of the natural order Simarubaceæ.

With regard to this bark, which is not mentioned by Martius, Dr. Barnsley states that it is used in dyspepsia and in intermittent fevers, and that he has employed it in the latter with decided success. With the bark he sends a portion of white crystalline powder, which he says was given to him by a native forester and gold miner of the woods of S. Paulo, who was well acquainted with the medicinal herbs of that district, and who stated that he obtained it from this bark. This crystalline powder has been examined by Mr. S. Plowman, who finds it to be chiefly sulphate of quinine with a little hydrochloride. The barks of the Simarubaceæ are not known to yield quinine, hence it is probable that Dr. Barnsley has been imposed upon.

Saponacea.—This is a kind of soap berry, the fruit of a species of *Sapindus*, possibly of *S. divaricatus*, Willd., to which Guibourt refers the soap berries he received from Brazil,* and which is the only species mentioned by Martius.

* See 'Hist. des Drogues,' 6th edition, vol. iii., p. 591.

Dr. Barnsley states that he has made an excellent tooth-wash from them, and suggests that, perhaps, some species of this berry is used in making the London "Floriline."

Tayuyá.—This is a long slender root varying in size from quarter to one-third of an inch, scarcely branched, brown externally, internally of a paler brown, and full of large pores, which are easily visible to the unaided eye. The cortical layer is not very distinct. The taste is bitter.

Dr. Barnsley refers this root to *Trianosperma Tayuyá*, Mart., but Martius describes the root of that plant as being tuberous and turnip-shaped. The leaf sent with the root is apparently that of a *Trianosperma*; but as there are no tuberous roots with the *Tayuyá* received, it is probably the root of another plant of the same genus. An infusion, tincture, or extract of the root is used as a drastic purge. It has properties analogous to Elaterium. In the province of Rio it is a common plant.

Timbo.—This drug consists of a very large woody root or prostrate stem, three or four inches in diameter, and much branched. Externally it has a dirty-white colour, with numerous warts scattered over it, and is of a rough aspect, owing to depressions, scars, and a few transverse ridges; the smaller portions are, however, only wrinkled longitudinally. The central portion or meditullium of the root is yellowish white, with a number of fine horny concentric rings; the bark of the root is distinct, thick, and starchy, and of the same colour as the meditullium. The taste is not bitter. When chewed the root causes only a slight but persistent tingling of the tongue.

According to Martius it is the root of *Paullinia pinnata*, L., and possesses acrid and narcotic properties, acting especially on the kidneys and brain; he compares it to aconite and states that the negroes prepare a slow poison from it. Dr. Barnsley is inclined to think that the above-named plant does not produce it, but that it is the root of *Physalis heterophylla*, Nels. The leaves accompanying the specimen being imperfect it is impossible to say what the plant is, but the leaves are more like those of a Sapindaceous than of a Solanaceous plant. It seems to possess powerful poisonous properties which may perhaps be worthy of investigation.

Velamé or *Braço de Preguiça.*—This is the root of *Solanum jubatum*, Dunal. Through an oversight its description was not given under Braço de Preguiça. The root is in somewhat flexuose pieces, externally resembling belladonna root in colour, varying from half to one inch in thickness. Internally the root is woody, the meditullium being of a pale yellowish colour with very numerous medullary rays, which are not visible to the naked eye, but are readily seen with the aid of a lens. The cortical portion is very thin and seems to consist of several extremely thin layers; the outer layer when scraped with the nail or with a penknife shows that the under layers are of a pale lilac grey colour and chalky appearance. This character does not occur in any other root with which I am acquainted, and at once distinguishes this drug. It appears to be almost tasteless. It is used for the same purposes as the leaves described on p. 905. Martius does not mention either Velamé or Panacea in connection with *Solanum jubatum*, Dunal.*

* In Martius, 'Syst. Mad. Med. Brazil,' Braço de Preguiça is referred to *Solanum cernuum*, Vell. This is a synonym of *S. jubatum*, Dunal.

THE SALICYLATE AND CARBOLATE OF QUININE.*

BY JULIUS JOBST.

In a communication to the *Pharmaceutische Zeitung* (No. 11, 1875), Schering states that salicylic acid forms with quinine a salt insoluble in water, and soluble in alcohol, which is not crystallizable. The author of this paper, on the contrary, states that an aqueous solution of hydrochlorate of quinine gives in the cold with salicylate of ammonia (prepared from Kolbe's salicylic acid) a cheesy precipitate of salicylate of quinine, which can afterwards be obtained crystallized from alcohol in wonderfully fine perfect prisms in concentric groups. The same compound is formed when an alcoholic solution of quinine is mixed with an alcoholic solution of salicylic acid to complete saturation, and the alcohol is afterwards slowly evaporated.

The salicylate of quinine is anhydrous. A determination of the quinine by the author gave the formula $C_{20}H_{24}N_2O_2$, $C_7H_6O_3$. The salicylate of quinine dissolved in a small quantity of water upon the addition of some dilute hydrochloric acid, and was precipitated with ammonia. The resulting precipitate of quinine was collected upon a filter, and the quinine dissolved in the ammoniacal filtrate extracted by means of ether. The above mentioned formula required 70·12 per cent. of quinine. The first experiment gave 69·66 per cent., the second, 70·17 per cent.

Salicylate of quinine dissolves in 225 parts of water at 16° C., in 20 parts of 90 per cent. (by volume) alcohol at 13° C., and in 120 parts of ether at 16° C.

Since the crystallized salicylate of quinine could be so easily obtained, the author turned his attention to the carbolate, which has already for some time been in no inconsiderable demand for medicinal purposes, but which hitherto has only been met with in pharmacy in a pulverulent form, and of varying composition and properties. He reports that he has succeeded in preparing the carbolate of quinine, both from water and from alcohol in slender acidular crystals. Dried at 130° the carbolate gave the formula $C_{20}H_{24}N_2O_2$, C_6H_6O. This formula requires 77·51 per cent. of quinine. Three analyses gave respectively, 77·52, 77·32, and 77·88 per cent.

Carbolate of quinine dissolves in 400 parts of water at 16° C., in 80 parts of 90 per cent. alcohol at 13° C., and slightly in ether.

If it could be assumed that the quinine salts of salicylic and carbolic acids have a similar therapeutic action, then the greater solubility of the salicylate would gain for it the preference. In any case the author considers that henceforth for the carbolate only the definite crystallized compound should be used in medicine.

* 'Neues Repertorium für Pharmacie,' xxiv., 193.

THE CONSTITUENTS AND PROPERTIES OF THE GENUS POTENTILLA.†

BY JOHN M. MAISCH.

The genus *Potentilla* belongs to the natural order of Rosaceæ, tribe Dryadeæ, and comprises mostly herbs, together with some shrubby plants, which are indigenous mainly to the temperate zones of the old and new continents. The generic name appears to have been formed

† *American Journal of Pharmacy* [4], v., 109.

from *potens*, powerful, in allusion to the reputed medicinal properties of some of the species. At the present time there are but few drugs officinal in any of the pharmacopœias which are obtained from plants belonging to the Dryadeæ, the most important being kousso, the inflorescence of *Brayera anthelmintica*, Kunth, and tormentilla, the rhizome of *Potentilla tormentilla*, Sibthorp ; s. *P. erecta*, Nestler ; s. *Tormentilla erecta*, Lin.; s. *T. officinalis*, Smith. The former, which, by Endlicher, is placed in the suborder Spiræeæ, but amongst the Dryadeæ by De Candolle, contains in its dry condition, besides very little volatile oil, a considerable proportion of tannin, some koussin, resins, etc., to which it owes its taste, which at first is somewhat astringent, but afterwards bitter and to a certain degree acrid. The latter, tormentil, has, when fresh, a rather roselike odour, which is lost by drying, after which it retains an astringent taste, due to the presence of a considerable quantity of tannin, from which the so-called tormentil-red, the red colouring matter of the drug, which is likewise present to the extent of about one-sixth of the weight of the rhizome, is probably a derivative.

Similar constituents will doubtless be found in the roots and herbs of the plants which are botanically allied to the genus *Potentilla*, if we may be allowed to judge from their sensible properties. The following plants of the suborder Dryadeæ (De Candolle's tribes of Sanguisorbeæ and Dryadeæ) contain in their roots and herbaceous portions very little or no volatile oil, as is evidenced from their slight odour, but they possess a more or less marked astringent taste, in some cases accompanied by some bitterness: *Geum rivale*, Lin., and *G. urbanum*, L., or avens ; *Poterium sanguisorba*, Lin., and *Sanguisorba officinalis*, L., or burnet ; *Alchemilla aphanes*, Lærs (s. *Aphanes arvensis*, Lin.), and *A. vulgaris*, L., or lady's mantle ; *Agrimonia eupatoria*, Lin., or agrimony, and *Rubus villosus*, Aiton, and *R. canadensis*, Lin., the North American blackberry and dewberry, the rootbark of which is officinal in the U. S. Pharmacopœia.

Of the genus *Potentilla*, of which about one hundred species are enumerated, tormentil is the only one occasionally still used in medicine, though formerly several species now obsolete have been employed.

Potentilla anserina, Lin., silver weed, is indigenous to Europe and the northern portion of the American continent. Both the herb and the perennial root have a mild astringent taste, and are said to have been used by the Indians as an antidote to snake-poison; while in Europe, it was employed in diarrhœa, hemorrhages, pulmonary complaints, some hepatic disorders and in dropsy. The leaves are radical, interruptedly pinnate ; the leaflets, 9 to 19 in number, oblong, deeply serrate, silvery white and downy underneath.

P. fructicosa, Lin., shrubby cinquefoil, likewise inhabits the northern portions of the Northern hemisphere. The five to seven pinnæ are linear to lanceolate oblong, entire, silky underneath, and have a mild astringent and bitterish taste. They are used by some Siberian tribes like tea, and were formerly reputed to possess febrifuge properties ; externally, the leaves were used as a vulnerary.

P. rupestris, Lin., is a native of mountainous regions of Europe and Siberia. The radical leaves are pinnate, and the stem-leaves usually three-lobed ; they have an astringent taste and are used in Siberia like tea.

P. palustris, Scop., s. *Comarum palustre*, Lin., marsh-cinquefoil, occurs in cool, boggy localities of the Eastern and Western hemispheres. It is easily distinguished from the preceding and following species, which bear yellow flowers, by its dark purple petals. The three to seven leaflets are oblong-lanceolate, sharply serrate, hoary beneath, and have a somewhat astringent taste.

The species just mentioned have the leaves pinnate; in the following they are palmate, and mostly composed of five leaflets :

P. argentea, Lin., silvery cinquefoil, occurs in dry localities of the old and new world. The wedge-oblong leaflets are entire towards the base, deeply incised, and almost pinnatifid near the apex, green and smooth above, and silvery canescent beneath ; their taste is astringent.

P. tormentilla, Sibth., tormentil, a native of Europe, grows in meadows, and has obovate or wedge-lanceolate, deeply-serrate, green and somewhat shining leaflets, possessing an astringent taste, similar though somewhat weaker than the rhizome.

P. reptans, Lin., creeping cinquefoil, is a European and Asiatic plant, growing in damp localities. Its thin, creeping stems bear solitary flowers on long peduncles, and are of a golden-yellow colour; the leaflets are elliptical to oblong-obovate, sharply serrate, bright green and slightly hairy above, paler and somewhat pubescent beneath. The taste of the root and herb is sweetish and astringent. This plant (or the tormentil) was probably the *pentaphyllon* of the ancients.

As far as may be judged from the taste, and from the few published chemical experiments, all the species enumerated before contain some tannin, upon which the comparatively feeble medicinal properties mainly depend. The indigenous *P. canadensis*, Lin., the common ciquefoil, or five-finger, resembles the former in taste, and, like them, may be supposed to act like a mild astringent. In the January number of the *Charleston Medical Journal and Review*, however, this plant is highly recommended for other purposes. Dr. Wm. Hauser, of Bartow, Jefferson county, Georgia, writes of it as follows:—

"It is the best and most powerful *sudorific* I have ever found. And like all of its class, it is, under certain circumstances, diuretic also. Dr. Edwin Le Roy Anthony, son of Dr. Milton Anthony, founder of the Medical College of Georgia, assured me, many years ago, that he had cured gonorrhœa with it. But my purpose, in this short article, is to ask the attention of the medical profession to it in the treatment of peritonitis of any kind, but especially *puerperal peritonitis*. In a large practice of more than twenty years, I have never found anything, nor all other things combined, to equal this simple plant in the treatment of this exceedingly painful, dangerous and sometimes stubborn disease. I have never failed with it once in all this time, to the best of my recollection. A recent case that gave much trouble and anxiety to two of my honoured medical brethren, has brought it afresh to my mind, though I have not been in practice myself for eight years. My method with it is simply this:—Make as strong a decoction of the plant (leaves, vines, and roots) as possible, and give the patient, at any stage of the case, large draughts of the tea, as hot as she can drink it, every half hour, or oftener, till she be thrown into full perspiration. All pain and fever will soon be gone, and then you have the entire mastery of the case."

Some years ago, Dr. Richard Moore, of Sumter District, S. C., called attention to this plant as an efficient and useful remedy in the treatment of chronic colds, threatening phthisis ; he used it in the form of decoction.*

Both Dr. Moore and Dr. Hauser name the plant employed by them *Potentilla reptans*. The Linnean plant bearing this name, however, is a native of Europe and Asia, and does not occur in this country; it is represented on this continent by *Potentilla canadensis*, Lin., which resembles it, and is a rather variable species, growing in dry fields and moist thickets. *P. sarmentosa*, Wild., *P. caroliniana*, Poir., *P. simplex*, Michaux, and *P. pumila*, Pursh, are now regarded as mere varieties of this species, which occurs from North Carolina to Mississippi, and northward throughout Canada. The plant is, however, distinguished from *P. reptans*, by the latter having many slender, nearly smooth and purplish stems, the leaves on longer petioles, leaflets elliptical to obovate, obtuse, serrate, and somewhat hairy, the lateral pairs approximate, or united at base; stipules small oval-lanceolate, entire or few-toothed; petals yellow, obcordate. *P. canadensis* has even the summer

* See 'Resources of the Southern Fields and Forests.' By Dr. F. P. Porcher, 1869, p. 166.

runners thicker, green, or occasionally purplish, always silky hairy; stem-leaves on shorter petioles; leaflets obovate-oblong, rather acute, coarsely serrate, hairy; stipules ovate, acutely toothed; petals roundish obovate, entire or notched.

The botanical characters, it will be observed, are sufficiently distinct for the two species, although their sensible properties are alike as far as odour and taste are concerned. It is scarcely to be supposed that the American plant be possessed of more potent properties than the majority of the plants of the same genus and tribes mentioned above; but the statements made of its efficiency are such that they invite to a carefully undertaken trial.

THE OCCURRENCE OF ORGANIC FORMS IN CONNECTION WITH CONTAGIOUS AND INFECTIVE DISEASES.*

BY J. BURDON SANDERSON, M.D., V.P.R.S.,

Jodrell Professor of Physiology in University College, etc.

LECTURE III.

(*Concluded from page* 970.)

It has been sought to answer this question in two ways: on the one hand, by separating the rods from the liquid, and determining their pathological properties by experiment; and on the other, by testing the activity of the liquid after the rods have been removed from it by some process of filtration, The first of these methods—that employed, or rather attempted, by Davaine and the French experimenters—has led to no result; and it is difficult to see how it could yield any; first, because complete separation of such organisms from the medium in which they are contained is impossible; and, secondly, because, in the very act of filtration, the organisms themselves would probably undergo such changes as would entirely alter their properties. If, as is probable, the activity of the rods is dependent on their vital functions, there is no reason to anticipate that they would continue to manifest that activity when "out of their element;" still less that it would show itself in any descendants or progeny obtained from them by the method of cultivation. The other method has been used by Klebs and Tiegel. These observers have found that, just as it is possible to separate the bacteria contained in ordinary septic products from the liquid in which they are suspended by filtering them under pressure through a stratum of porous porcelain, the same method can also be successfully applied to blood containing the rods of splenic fever. The result of the experiments which, it must be admitted, were not so frequently repeated as could have been wished, was, that the filtrate of blood (or rather the liquid of the spleen of a diseased animal), of the virulence of which experimental proof had previously been obtained, was found to be incapable of communicating the disease. Clearly there is no proof in this fact that the contagium of splenic fever is exclusively contained in the rods; but there is proof in it that the agent is, as we believe all other contagia are, a body which is incapable of solution or diffusion, and which attaches itself to concrete particles.

An additional and, to my mind, more satisfactory proof of this lies in the remarkable observation made by Brauell, that, when pregnant animals are affected with splenic fever, the blood of the embryo is not contagious. Brauell found in repeated trials that, in such animals, blood from the fœtal circulation could be inoculated without result. Here the placental apparatus serves not merely as a filter, but as a diffusion-cell, keeping back not merely solid particles, but everything which is not capable of passing through animal membranes. This fact—of the immunity of the fœtus—must be taken in connection with the incommunicability of the disease excepting by actual transference of blood.

The contagium of splenic fever is wonderfully persistent. With reference to this point, there is an apparent antagonism of facts, which, however, on examination, turns out to be a perfect agreement. Brauell found that blood, after removal from the body, loses its activity in a few days. On the other hand, we are certain that the contagium must have a state of existence in which it is in the highest degree permanent and indestructible. Thus Bollinger gives an account of what may be called a stable-enzootic of splenic fever, in which ten cases occurred in one stable during a period of three years, no other cases occurring in the neighbourhood. The contagium must have remained latent during the whole period.

What does this mean? Here is a disease only transmissible by inoculation, and of very short duration. Why does it not perish out of existence? Clearly it would do so had it not some as yet unknown means of perpetuating itself. How it does so it would be too bold to conjecture. The rods can hardly be supposed to be the means of perpetuation; for like the contagious property which they perhaps represent, they are very fugitive, and, in particular, like it, and along with it, they disappear at the moment that putrefaction commences. It is therefore not possible to refer to them as contrivances suited for the storage of contagium, or for its conveyance to a distance, for either of which purposes they are obviously unfit. This very consideration, however, can, I think, be made to appear rather as an aid to our understanding of the relation between organization, or rather living organic forms, and contagion, than as a difficulty or objection. For, if we turn from the specific form to what we know about the development and life-history of common bacteria, and, indeed, of the beings belonging to the same group in general, we find the same thing. Just as in the case of the specific contagium we are compelled to recognize two states of existence, one enduring and latent, the other active but fugitive; so among these organisms we find one condition in which the growth and multiplication of individuals is very active, but individual life is extremely short; another in which the vital activities of the organism are stored up for the future, the individual being for this very end endowed with the power of resisting external disintegrating agencies, and thereby of enduring for an indefinite period. Thus, without any effort, we find, in all probability, in the life-history and development of the organisms, the counterparts of all the phases of the process of contagion.

During the last few years, the pathology of splenic fever has acquired an even wider interest than it had before, from the publication of a series of cases of a rapidly fatal disease affecting the human subject which presents the characters of splenic fever, and turns out, on investigation, to be identical with it. The first of these cases was published by Professor Buhl, at Munich, in 1868. It was that of a man aged thirty-two, who died after a short illness, of which collapse and vomiting were the chief symptoms. After death, the stomach and duodenum were found to be the seat of circumscribed foci of submucous infiltration, presenting characters similar to the so-called "carbuncles" of the intestine seen in the horse. The rods of splenic fever presented themselves in the blood, and the other lesions corresponding to those of the disease in question were found.

The affection was termed by Buhl "*Mycosis intestinalis.*" Shortly afterwards, two other cases were recorded by Professor Waldeyer, now of Strasburg. In one of them, that of a slaughterer, whose occupation pointed to the sources of infection, the nature of the disease was suspected during life. After death, the suspicion was confirmed by the complete correspondence of the lesions with those of splenic fever in the horse. As in Buhl's case, the microscopical investigation showed that masses of zooglæa existed in the affected tissues, and that rod-like microphytes were to be found in the circulating blood, particularly in that of the portal vein. Other rapidly fatal cases have since been recorded, all of which

* Lecture delivered at Owens College, Manchester; reprinted from the *British Medical Journal.*

exhibited pathological appearances of the same kind, the most constant being the enlargement of the spleen and the circumscribed hæmorrhagic infiltrations of the intestines, resulting in more or less extensive sloughing of the mucous membrane, and associated with serous exudations, infiltration of the subserous tissue, and hyperæmic enlargement of the lymphatic glands in relation with the infiltrated parts.

Whatever doubt remained as to the identity of mycosis intestinalis with splenic fever, was removed by the appearance of a communication by Dr. Münch of Moscow, who was able to state, from the results of his own dissection in the "Workman's Hospital" at that place, that in all the cases which he had occasion to examine the bodies of men who had died of disease contracted by infection from animals, the intestinal lesions and the condition of the other internal viscera corresponded closely with those described by Buhl and Waldeyer. In these, as in many other cases recorded by the best observers, the primary pustule (*pustula maligna*) at the seat of inoculation, often supposed to be the one pathognomonic lesion of splenic fever in man, was by no means a constant feature. Out of twenty-eight cases recorded by Münch (1867–71), seventeen exhibited a primary pustule, which in all but two was carbunculous; but, in the other eleven cases, there was nothing whatever to be found on the skin.

As regards the morphological relations of the organisms found in mycosis intestinalis with those of splenic fever, further investigation is required. So far as the former have been described, they agree completely with the others, as may be readily seen by comparing the drawings of Wagner, taken from a case of mycosis, with Cohn's or Bollinger's representations of the rods of splenic fever.

The identity of the two forms being admitted, Buhl's and Waldeyer's anatomical investigations afford a key, which was before entirely wanting, to the understanding of the so-called "localizations" of splenic fever in cattle. This key consists in the demonstration that the formation of foci of infiltration, of which we read so constantly and repeatedly in the descriptions of the veterinary pathologists, is a process of which it is the characteristic that the tissues of the infiltrated part became infested by myriads of microphytes of a particular kind, so that the presence of these bodies is as much a part of the process as the emigration of the colourless corpuscles from the blood-vessels is a part of ordinary suppuration. Further than this it is not possible to go, until the initial stages have been investigated in the lower animals.

I now pass to a disease which in two or three respects resembles splenic fever, while it differs from it in a great many more. As regards its mode of diffusion, there is this striking resemblance, that, although relapsing fever does not require inoculation in order to communicate itself from the sick to the healthy, the area within which its contagium can act is very limited. If a patient be introduced into a ward, the patient in the next bed may be attacked, but the disease does not spread. In the recent epidemic at Breslau, to which I am about to refer, there were many instances in which the disease found its way into rooms inhabited by several families, and it was then observed that the members of one family (in other words, those who lay on the same heap of straw) were attacked one after another, while the other occupants of the room remained exempt.

Another striking point of resemblance lies in this, that they are both pre-eminently blood-diseases. In the case of splenic fever, we have direct evidence of this in the fact that the disease is conveyed by transfusion of blood. Whether this is also true as regards relapsing fever has, of course, not been ascertained; but we have, as indications of the blood-affection, first, the fact that the spleen, of which the function is intimately connected with the blood, is enlarged in a similar way in both diseases; and, secondly, the fact which at the present moment specially interests us—the recent discovery that, in the blood of persons suffering from relapsing fever, organisms exist, which, from their remarkable form, are called *spirilla*.

During the prevalence of relapsing fever in Berlin in 1872, Dr. Obermeier, who had, in the previous epidemic of 1868, been engaged in microscopical investigation of the blood, announced the discovery of the spirilla in a communication made to the Berlin Medical Society. This communication was based on twelve cases, in all of which the organisms were observed. On March 26th, Dr. Obermeier published a second series of observations; twenty new cases had been investigated, in nine of which the blood had been examined daily. The results of these examinations showed, that the presence of the organisms in the blood was associated with the morbid process so closely, that as soon as the pyrexia disappeared they disappeared with it, reappearing when the patient again fevered in the relapse.

Soon after the death of Dr. Obermeier, a third series of observations was communicated by Dr. Engel to the *Berlin Medical Weekly Journal*, founded on the examination of the blood in eighteen cases in the Charité Hospital at Berlin, under the care of Professor Frerichs. They confirmed in every particular the statements of Obermeier, deriving additional value from the exact observations they contained as to the time which intervenes between the onset of pyrexia and the first appearance of the organisms.

During the same year, the epidemic prevalence of relapsing fever at Breslau afforded additional opportunities for investigating the subject. The first results of these inquiries were communicated by Dr. Weigert to the Silesian Scientific Society on September 12th, 1873. The clinical relations of the subject have since been worked out by Dr. M. Litten in a report on the epidemic founded on observations in the General Hospital in Breslau.

In this report, Dr. Litten has given by far the most complete account of the spirilla that has yet been published. He confirms the statement of Obermeier that they are found only in the blood of persons affected with the disease. In more than one hundred cases they were never missed. They occurred only during the paroxysms, and invariably disappeared before the fall of temperature—never remaining during the period of apyrexia. Their number, however, varied considerably; they were sometimes so numerous as to crowd every field, at others they were difficult to find. Dr. Litten describes their motions as partly consisting in undulations which progress along the course of each fibril, and partly in oscillatory movements, *i.e.*, alternate flexions and extensions, springing from some point in the course of the fibril.

Dr. Litten made some very interesting observations on the relation of these remarkable bodies to temperature. He observed that on raising the temperature of the stage of the microscope gradually to 60° C., no effect was produced. As soon as this point was passed the movements became languid. By the time that 65° was reached they had entirely ceased. No effect was observed on cooling the preparation to the temperature of freezing. When it was kept for some time on ice, the movements finally disappeared.

Here I stop. I have brought before you, to the best of my ability, the leading facts relating to the only four cases known to me in which the connection between organic forms and specific diseases has, as yet, been satisfactorily made out: those of cow-pox, sheep-pox, splenic fever, and relapsing fever. These four diseases, although they are so different, are associated by the fact that each of them presents very well-marked nosological specificity—in other words, they are all of them characteristically contagious diseases. Small-pox we must not yet include, excepting on the ground of identity with cow-pox; but we may hope that the researches of Dr. Weigert, as soon as they appear, will afford us material for conclusions on this subject. In the meantime, let us carefully guard against undue precipitation, in the process of combining the few facts we are already in possession of into a system. The desire to discover the practical bearing of his results on the all-important questions of prevention and treatment is a constant and ever recurring temptation to the scientific pathologist, seducing him from his path of patient and silent investigation into speculations about the origin and nature of disease which, even though they may sometimes lead to useful practical applications, have no permanent value.*

THE PREPARATION OF SALICYLIC ACID DRESSINGS.

The following information respecting the use of salicylic acid in the preparation of antiseptic dressings is taken from a translation of a paper by Dr. Thiersch, "On Lister's Antiseptic Method, and on the Substitution of Salicylic for Carbolic Acid," which has appeared in the *Medical Record* for May 26, and June 2 :—

Dr. Thiersch regards the antiseptic action of the salicylic dressing as certain as that of Lister's carbolic dressing. The salicylic acid also possesses two advantages ; it is less irritating, and is not volatile. It can thus be incorporated with the dressing in greater quantity and remain for a longer time in contact with it, without endangering the result. Another advantage of salicylic acid is that it is inodorous.

For dressing with salicylic acid there should be kept at hand a supply of salicylic water—a solution of one part in 300; and of salicylic cotton, containing respectively 3 and 10 per cent. Dr. Blaser, the apothecary of the Jacob's Hospital, makes the preparations in the following way. *a.* For 3 per cent. salicylic cotton, 750 grammes are dissolved in 7,500 grammes of spirit of spec. grav. 0·830 ; the solution is then diluted with 150 litres of water, at a temperature from 156° to 176° Fahr. ; and the mixture is used to saturate twenty-five kilogrammes of cotton-wadding freed from fatty matter. *b.* The 10 per cent. salicylic cotton is made by dissolving one kilogramme of salicylic acid in 10,000 grammes of spirit of spec. grav. 0·830, adding 60 litres of warm water (as above), and saturating with the mixture 10 kilogrammes of cotton-wool. The saturation of the cotton is best done in a large shallow wooden tub ; and it is best to use only a small quantity of cotton-wool (two or three kilogrammes) at one time, as in only this way an equal distribution of the salicylic acid is possible. The proceeding occupies only a short time.

In charging the cotton-wool with the warm solutions of salicylic acid, it is introduced in layers, moderate pressure being applied to each layer, so that it may be completely saturated before another is introduced. After the proper quantity of cotton-wool has been introduced and is perfectly saturated, the whole is inverted, and allowed to stand for a short time (about ten minutes), so that the solution may be diffused as equally as possible. The cotton-wool is then laid in small heaps to cool, during which process the salicylic acid crystallizes ; and it is then allowed to dry in a moderately warm place for about twelve hours. It is not advisable to hang it up, as, in the process of draining, the equal distribution of the acid is disturbed. The salicylic acid may not crystallize in equal amount in all parts of the wadding ; and even after drying, the distribution of the acid may be rendered unequal by handling. Thus, in many parts there will be less than 3 per cent., in others more. An addition of 1 per cent. does no harm ; but if in the 3 per cent. cotton-wool there be a deficiency of 1 per cent., or in the 10 per cent. cotton of 3 per cent. the deficiency should be made up from portions containing an excess.

The salicylic cotton-wool does not allow the passage of the discharges of the wound so readily as Lister's carbolic gauze ; and hence, when a dry salicylic acid dressing has remained for a week or two, pus is generally found in various quantities between it and the wound. Dr. Thiersch has made some experiments in order to find a more permeable material for dressing than cotton-wool. Hemp, flax, sawdust, etc., did not answer the purpose. His attention was then called to jute ; and, having obtained a supply of clean jute, he charged it with 3 per cent. of salicylic acid, adding also 20 per cent. of glycerine to prevent the acid from falling off in dust. He introduced 2,500 grammes of jute into a solution of 75 grammes of salicylic acid in 500 grammes of glycerine and 4,500 grammes of water, at a temperature of 158° to 176° Fahr. In this way he obtained a soft material, resembling flax, giving off but little dust, which, when left on a wound for nine days, completely absorbed thick pus, the pus becoming equally diffused through it. At the same time, the dressing remained inodorous, and gave in every part the reaction of salicylic acid on being tested with chloride of iron. On account of the equal distribution of the discharges from the wound in the jute dressing, it is not necessary to apply a strongly charged layer internally ; a 4 per cent. dressing is sufficient. Dr. Thiersch believes that jute will supersede cotton as a dressing for large suppurating wounds, although it is not to be compared with the latter as regards softness. Some comparative statements of the cost are given, to show that the salicylic acid dressing, especially when jute is used, is much cheaper than the carbolic acid dressing : the proportions, calculated for a case of amputation of the thigh, being:— Lister's dressing, 2·35 *mark*; dry salicylic dressing, 1·52 *mark* ; dry salicylised jute dressing, 0·92 *mark*.

The cheapest of all is the jute dressing ; and it is the more so, because it can be allowed to remain a longer time on the wound without danger of an accumulation of the discharges beneath it. Dr. Thiersch's experiments with the jute dressing are as yet, however, not sufficiently numerous to enable him to speak with absolute certainty about it. He does not think that it is of much importance whether a spray of carbolic acid (1 in 50 of water) or of salicylic acid (1 in 300) be used. Many give carbolic acid the preference, because it does not cause coughing and sneezing, and is readily removed from the clothes by evaporation. Dr. Thiersch prefers salicylic acid, because it irritates the wound less. The sponges are kept in a solution of carbolic acid (1 in 20 of water) ; and, after being used, are washed with much warm water and again placed in the carbolic acid solution. Salicylic acid solution may also be used.

SOME OF THE PHENOMENA ACCOMPANYING A CHANGE OF PHYSICAL STATE.*

BY THOMAS WILLS, F.C.S.,

Of the Royal Naval College, Greenwich.

Chemists are at the present time acquainted with, at the most, some sixty-three or sixty-four bodies which are called *elements*, so called from the fact that all attempts to resolve them into anything other than themselves have hitherto failed, and because it has been found that all material things, without exception, are composed of one or more of these substances united together in different ways. We may allow our imagination to regard these *elements* as the *bricks of the universe*. I have here written upon this table a list of these bodies, many of which are very well known, others are mere chemical curiosities.

Now if I could place before you a specimen of each of the substances mentioned here, there would be no two found alike, but all would possess more or less diverse properties and characteristics, but at the same time it would be seen at once that three well marked divisions might be made, owing to the occurrence of two distinct breaks in

* Since this lecture was delivered, the first part of Dr. Weigert's 'Researches' has been published at Breslau, with the title 'Anatomische Beiträge zur Lehre von den Pocken.'

* Lecture delivered before the Bristol Pharmaceutical Association, April 30, 1875.

physical state. Thus, it would be found that out of these sixty-four elements fifty-seven would appear as solid bodies, two as liquids, and four as gases, leaving one the physical state of aggregation of which has not yet been determined. Let us at once clearly understand what is meant by these terms solid, liquid, and gas. Here, for instance, is a block of wood; it resists the pressure of my fingers; it has a well-defined form, and it maintains that form, which in this case is cubical; the particles of which the wood is composed are evidently not free to move, but remain in one position, and we speak of matter having these characteristics as being in the solid condition. Here, however, is a basin of water; I plunge my hand into the water and it gives way; the water, you further observe, has no particular form of its own but takes the form of the vessel which retains it, some vessel being necessary for its retention; also this water, and bodies in a like condition, when left free to move, present a well defined and perfectly level surface: here it is evident that unlike the particles of wood, the particles of water are to a large extent free to move about amongst themselves. Matter with these properties is in the liquid state.

Enclosed within this bladder is some of the ordinary air which may be taken as a fair example of gaseous matter; such matter offers very little resistance to the passage of one's hand through it; it presents no surface as the water does, and it requires a completely closed vessel to retain it, and, at the same time, it completely fills any vessel in which it may be kept; it is here obvious that there is little or no power holding the particles of gaseous matter together, as their tendency is rather to get as far from each other as possible, and to fly apart.

From these observations we may conclude that the cause of the very great difference in physical properties between these three states of matter is to be found in the presence or absence of a power binding the particles of a body together. This power or force is called cohesion; and such a force acts between the similar particles of the same body. We have no difficulty whatever in recognizing this cohesion in solid bodies; in its absence no solid could exist. In liquids this cohesion is to a large extent wanting, nevertheless it may be shown that it still exists, but in a much weaker state. Liquids, when placed on a level surface and left to themselves, show a tendency to form themselves into drops, and water, if freed from air, obtains more of the properties of a solid body. In gases we fail to find any trace of cohesion, for, as was mentioned previously, the particles of a gas have rather a tendency to fly away from each other. In furtherance of our object we shall now inquire whether the amount of cohesion possessed by any particular body is fixed and certain, or whether we can so alter its amount as to alter the physical state of the body itself.

The question as it is put here is intended only to make our ground quite clear, for you will see at once upon a moment's reflection that we can and do do this continually, and hence it follows that when speaking of the state of a body we must take into account the circumstances under which it is existing.

Thus it has been previously mentioned that amongst the sixty-four elements, are to be found two liquids, the one bromine and the only liquid metal, mercury, but this remark only applies under ordinary existing circumstances. The liquid bromine will become a gas at the tropics, and the liquid mercury a solid at the poles. Now that difference of circumstances at the tropics and the poles which affects the state of these two bodies is one of temperature only. The force of heat then is antagonistic to the force of cohesion, and consequently tends to lessen its effect, and we should feel inclined to argue that the same substance under different conditions of temperature might be made to assume different states of aggregation. Taking for illustration two other bodies, solids, from the list of elements, viz., lead and iodine, and subjecting them to the action of heat, that is to say, raising their temperature, we see the result—the lead becomes a liquid and the iodine a gas. Here, work has been done, this work consisting in the separation of the molecules of which the lead or iodine is composed and in doing this work a certain amount of heat has been consumed. On the return of either to their previous condition this heat will be given up. Here, however, a point of some importance occurs. This consumed heat is not all expended in one direction; a part of it being used to increase the temperature of the body, such heat is at once recognizable by the thermometer and remains as heat; but another portion of this force is expended in separating the molecules of the body to a greater distance one from the other; that is the force of heat has been converted into another kind of force, and this amount is not recognized by the thermometer.

When the molecules of a body are in such proximity as to have a certain sufficient attraction for each other—viz., when there is present a certain amount of the force of cohesion, the solid state is maintained; separate them from each other so as to lessen this attraction and they obtain a certain freedom of motion amongst themselves and the passage into the liquid state is the result. The extent of the distance by which these molecules are separated when a solid becomes a liquid is, without doubt, very small; but even by this small interval their attractive force is largely destroyed.

This effect may be paralleled by an experiment in magnetism. A powerful magnet may be made to support a heavy weight from its naked poles; but if a small thickness of paper be interposed between the magnet and the weight it will be found that the weight cannot be supported.

When heat is first applied to a solid body it is invariably expended in these two directions, but at the moment when any portion of the solid begins to assume the liquid state, the whole of the heat applied to a body is expended in one direction only, that is in doing molecular work; and this continues to be the case until the whole of the substance has become a liquid, when again the heat is divided in two distinct ways, hence the temperature of a body remains constant during the process of fusion or liquefaction, no matter how much heat is being applied; upon resolidification this so-called *latent* heat is rendered manifest once more.

It is therefore necessary, before a substance passes from the solid to the liquid state, that it should be supplied with a certain fixed and definite amount of heat, and when solids are observed to become liquids we are perfectly sure that this heat has been obtained from some source or other. Experimental illustrations of these facts might be multiplied to a great extent. The effect of causing a solid to become liquid such as, for instance, the solution of a salt in water, is a cooling one. The solid in becoming a liquid requires an amount of heat which it obtains from the water in which it is dissolved, and thus this water is cooled; and if a liquid be caused to solidify, such as, for instance, the sudden crystallization of a solution of sulphate or hyposulphite of soda, the liberation of heat is at once recognized. At the moment when the passage from the liquid to the solid state takes place, a power of molecular arrangement seems to be active, and the molecules show a decided tendency to unite together in a certain particular and characteristic manner, and in this way geometrical structures of extreme beauty are developed as if by a natural growth, and thus we have the marvellous phenomena of crystallization, as it were a link between the inorganic and organic kingdoms, crystallization resembling very closely in some respects the building up of vegetable structures.

Crystals are formed in a perfectly regular way, each crystallizable substance having a characteristic form of crystal, and the angular measurements of each crystal of the same substance are always found to be alike. By this means, as you are aware, crystallographic systems have been arranged, the study of which, however, has by no means become so general as would no doubt be desirable. One, probably the great, point of interest attached to this subject, is, that it brings us face to face with molecular action and reveals to us a little of the more subtle work of nature, and it will probably be from this or some allied source that future knowledge regarding atomic and molecular arrangement will come. Already, in the hands of such men as Dr. Tyndall and Professor Mitscherlich, the subject has proved fertile in this direction.

We have hitherto been confining our attention to those phenomena which are connected with the solid and liquid states of matter, but the facts which have been stated regarding the circumstances under which one state passes into the other are equally correct when applied to the liquid and gaseous conditions.

There appears to be a much greater distance between the liquid and gaseous states than between the solid and liquid, but it is probable that every substance which can be subjected to heat without decomposition, can by such means be caused to pass through all three states, the liquid state occupying the intermediate position. The usual effect of heating a solid body is first to convert it into a liquid and then into a solid, water affording an excellent illustration of this effect.

The molecular work done, however, in the conversion of a liquid into a gas is much greater than that done in the liquefaction of a solid. The separation of the molecules is much wider, and they are altogether released from the force of cohesion; hence the difference in bulk between the gas or vapour produced and the bulk of the liquid producing it is extremely large. A cubic inch of water, for example, becomes, when vaporized, speaking roughly, a cubic foot of steam.

Now in the case of the conversion of a liquid into a gas, as before, heat is consumed in direct proportion to the work done, and is also expended in two directions, a portion of it remaining latent being converted, as it were, into an elastic spring keeping the gaseous molecules apart, while another portion is recognized as giving to the gas or vapour a certain elevation of temperature.

At a point called the boiling-point, of which something more will be said hereafter, liquids pass into gases with the utmost ease, and this point, like that of liquefaction, is one at which a constant temperature is maintained until the whole of the substance has changed its state, all the heat during this interval being consumed in doing molecular work. On the return of the vapour to the liquid state this heat once more becomes manifest.

As a solid on becoming a liquid is cooled by abstracting the heat from the medium surrounding it, so a liquid on becoming a gas cools those objects which may be in contact with it. In this way the evaporation of water from the earth's surface exerts a cooling effect upon the earth and upon the atmosphere, so also cold sometimes of extreme intensity is obtained by the evaporation of volatile liquids such as ether.

As the physical state depends upon the distance of the molecules of a body from each other it would appear quite reasonable to expect that the application of some force other than heat which should bring these molecules into closer approximation would be accompanied by a change of state. If mechanical force be applied in order to obtain such a result, it is found that liquids yield very slightly to such force, so slightly that it is found impossible by the application of even the greatest mechanical force at our command to bring the molecules of any liquid sufficiently close as to cause such a liquid to become a solid.

With gases, however, the case is very different, the ease and the extent to which they yield to compression being extreme, under these circumstances it is quite possible to cause a change of state, and thus we have the liquefaction of gases. It will be evident that if there be in gaseous matter a certain amount of heat, not evident to us as heat, but as a molecular motion, it will be possible to convert a gas into a liquid in two ways,—in the first place, by abstracting this equivalent of heat, whereby the molecular motion will cease, or, secondly, by overcoming and destroying such motion by a superior force, whereby the equivalent of heat will be liberated as recognizable heat. In other words, a gas may be liquefied by either exposing it to great cold, or by forcible compression; by one of these means or by both combined many gases have been successfully liquefied. Much interest is attached to such liquefied gases.

I have here a vessel containing a considerable quantity of such a liquefied gas,—carbonic acid gas; this gas requires for its liquefaction a considerable pressure, as much as thirty-five atmospheres or more than 500 lbs. upon the square inch. The compression has been effected in this case by a powerful steam compressing pump, and during its compression the heat which existed as molecular motion was squeezed out of it, this vessel having to be well cooled during the operation to prevent its becoming too hot. Now I will ask you what will happen should this great pressure be suddenly released? We know that the tendency of the liquid would be to fly off as a gas once more, but in order to do this it is necessary that the equivalent of the molecular motion necessary for the assumption of the gaseous state must be supplied to it in the form of heat. From whence is this heat to come? Surrounding objects do not afford a sufficiently prompt supply, so that the evaporation of the first portion of the liquid absolutely abstracts heat from another portion, which is immediately lowered in temperature thereby. But observe the effects of this. By this extreme and rapid cooling the molecules of the liquid carbonic acid are drawn so close to each other that the liquid state cannot be maintained and the liquid passes into a solid, this white solid is carbonic acid, its temperature is—100°, and by its means we may illustrate many of the effects of extreme cold. Water, bromine, and mercury (which freezes at a temperature of—40°) may be frozen with the greatest ease. We turn now to the evaporation of liquids.

Although it is only at a point which is spoken of as the boiling point that we see distinctly the passage of a liquid into a gas, yet at temperatures far lower than this most liquids gradually assume the gaseous state; even at the freezing temperature water will pass into vapour, and the gradual drying up of a pool of water, or of a wet towel, illustrates the fact; this evaporation takes place from the surface only. As the temperature is raised evaporation proceeds at a greater rate, until there comes a time when vapour or gas is formed in the interior of the liquid, and we have then the phenomenon of ebullition or boiling. This point is a perfectly definite one, and it is reached when the elastic force of the vapour given off is equal to the pressure of the superincumbent atmosphere. If this external pressure be lowered then, having less resistance to overcome, the boiling point is reached more quickly, or in other words ebullition takes place at a lower temperature. If the pressure be increased, then the contrary result is obtained. It has been already mentioned that the temperature after the boiling point has been reached remains constant until the whole of the liquid has been converted into vapour or gas.

A remarkable phenomenon is observed if a liquid be very suddenly heated when, instead of the liquid being immediately dissipated in the form of gas or vapour, a portion only of it is so converted, and this portion so vaporized serves to lift the remainder of the liquid out of contact with the heated surface or vessel, thus allowing it to maintain a comparatively low temperature, and very largely to retard its evaporation. This phenomenon is called that of the spheroidal condition, and it is observed whenever a liquid is allowed to fall upon an intensely heated surface—it is necessary that the temperature of this surface shall be sufficiently high. This point varies with different liquids; whenever the spheroidal state occurs the liquid is invariably prevented from touching the heated solid by the interposition of a thin film of vapour. This want of contact between the two bodies may be shown in a variety of ways. In an experiment arranged here, a battery and electric bell are joined in a circuit, which includes the heated surface and the water upon it; at the present time the only break in the circuit occurs between the drop of water and the hot plate. If, now, the temperature of the plate be allowed to fall, the film of vapour supporting the drop is abolished and contact is obtained, which is ascertained by the ringing of the bell.

Many remarkable results may be obtained in virtue of the spheroidal state; thus a moist hand may be passed with impunity through molten iron or lead, or protected by a layer of the vapour of ether the scalding effect of boiling water is destroyed.

It has been supposed that some boiler explosions have occurred under circumstances connected with the spheroidal condition. Water in this state gives off very little steam, but if the temperature of the supporting furnace falls sufficiently low for contact to be established, there is a sudden and large evolution of steam, which, no doubt, if taking place in a boiler, would produce an explosion. The difficulty has always been to account, except under gross carelessness sufficient in itself to account for an explosion, for the water getting into the spheroidal condition; but an observation of Mr. Barrett seems to simplify this matter slightly. He finds that water containing a little grease takes the spheroidal state with much greater ease and at a lower temperature than pure water; and this effect is so remarkable that I propose to show it to you.

Here are two glass vessels of water, in one of which a little soap has been dissolved, making the water slightly turbid; in a small furnace, I have here a copper ball, which is raised at the present time to a bright red heat. On taking the ball out of the furnace and plunging it immediately into the vessel containing the soapy water, no hissing is heard, but the ball is seen still at a bright red heat, beneath the surface of the water, surrounded by a layer of vapour; on taking the ball out of this vessel and placing it into the other, in which no soap has been placed, a loud hissing noise and the evolution of a quantity of steam announces that the ball has at once come into contact with the water, and is being cooled in the ordinary way. The experiment here made is one of great interest.

The passage of the solid into the liquid state and of the liquid into the gaseous is usually abrupt and sharply defined, but there is every probability that this passage is continuous and not abrupt as it appears, but that it occupies a definite interval of time. It is readily seen that the molecules of any solid body, starting from their closest position of proximity, and under the influence of heat moving away from each other, until they occupy the position required for the liquid state, must of necessity pass over all the intervening positions when the body can be neither a true solid nor a true liquid.

Again, the amount of cohesion present when a body is in the solid state must *gradually* decrease until it is reduced to that amount present when the body is in the liquid state, all intermediate quantities being present at some time or other, and once more, starting with the amount of heat necessary to maintain a body in the solid form and then increasing the heat until the minimum quantity has been supplied necessary for the assumption of the liquid state, the whole of the intervening points must have been passed over, when the body has more heat, or its equivalent molecular motion, than is necessary for it while in the solid state, but less than that required for the liquid, when in fact it is neither the one nor the other. This interval may be very minute, in some cases inappreciable, but it nevertheless exists, and, to a great extent demonstrates the continuity of the solid and liquid states of matter. The passage of ice into water probably takes place during an interval not greater than 0·1° C.

We are, however, familiar with some substances which at ordinary temperatures have intermediate properties, and with many others which at a greater or less elevated temperature show such properties; honey, treacle, glue, tar, etc., belong to the former, while we have solder, glass, sealing-wax, and many of the metals of the latter. One case in particular is worthy of attention, that of the element sulphur. At ordinary temperatures this body is a yellow brittle solid; when heated to a moderate temperature (115° C.) it melts and becomes a mobile liquid. If this liquid be now poured out into water it solidifies into the original hard and brittle sulphur, and, on this solidification it gives out all the heat it received during the process of liquefaction. If, however, the temperature of the melted sulphur be raised considerably higher than its first melting point it becomes suddenly (at 230° C.) thick and viscid as treacle; heated still higher it again becomes liquid (at 250° C.); if now the sulphur be again poured out into water the whole of the heat taken up during this liquefaction is not given up, a part being missing. On examining the sulphur in the water it is found to be very different from the first brittle solid, being a soft, flexible, spongy mass, a body evidently intermediate between the solid and liquid states. If this variety of sulphur be left to itself it gradually hardens and becomes converted into the hard and brittle variety, at the same time giving up precisely that amount of heat which was previously missing. Here we have an excellent illustration of this intermediate state, and its relation to cohesion and heat.

Our reasoning would, in the same way, apply to the liquid and gaseous states, but in this case we have good experimental evidence to show that these states are continuous.

In 1822 Cagniard de la Tour made a number of remarkable experiments, in which he sealed up volatile liquids in glass tubes and exposed them to an elevated temperature. At a particular point he observed that the liquid disappeared, and that the tubes became filled with matter in a condition neither liquid nor gaseous. More recently Dr. Andrews, of Belfast, has carefully examined this subject and finds that with all liquid bodies which do not decompose when heated that there is a point at which they are in an intermediate state between the liquid and gas. Thus with carbonic acid, at a temperature of 31° C., or 87° F. it is found impossible to liquefy this gas by any amount of pressure—but the gas is reduced to a condition in which though homogeneous it is neither liquid nor gas—under these circumstances the lowering of the temperature will reduce it to a liquid, the raising of the temperature convert it into a gas, but in neither case can any break of continuity be detected in the transition.

In concluding this lecture, let me say, that the importance of any subject can never be arrived at by a study, however close, of the subject alone; to do so we must look at it in its relation with respect to other subjects, upon which it may have, or which may have upon it, any influence whatever, and if the subjects brought before you in this somewhat fragmentary lecture be regarded in this light it will be seen that they possess very considerable importance. Time will not permit me to indicate the directions in which these subjects have such evident application, but this I feel I may safely leave to yourselves.

THE DETECTION OF MINERAL ACIDS IN VINEGAR.

The fact that the violet of methyl-aniline undergoes no change of colour in contact with acetic acid, whilst the least trace of a mineral acid changes it to a greenish-blue, is suggested by M. Witz as a ready method of detecting the presence of free mineral acid in vinegar. To ascertain the relative strength in acetic acid and in mineral acid it would be sufficient to ascertain by means of an acidimetric solution (1) the point of neutrality to litmus, which would correspond with the sum of the acids; and (2) the point of neutrality in respect to the methyl-aniline violet, which would correspond to the mineral acids only. The difference would give the quantity of acetic acid.

PRESENTATION TO MR. BAYNES, OF HULL.

On Friday evening, June 5, several of the leading members of the Hull Chemists' Association assembled at the Cross Keys Hotel for the purpose of presenting to Mr. James Baynes a testimonial of their esteem and recognition of the valuable service he has rendered to the trade in his capacity as one of the Council of the Pharmaceutical Society. An excellent dinner was provided, and between twenty and thirty gentlemen sat down, Mr. Anthony Smith (president of the association) filling the chair, and Mr. William Staning the vice-chair. After the usual prefatory toasts,

The Vice-President proposed "The Pharmaceutical Society," congratulating the Hull Chemists' Association on having one of its members on the Council, and another as its Local Secretary.

Mr. C. B. Bell responded, and in the course of his remarks expressed the hope that the Pharmaceutical Society might long continue as their legal head. He trusted that none of the innovations that might be brought in with the idea of clipping the wings of that Society would be successful; but that it might continue in the honest straightforward course it had ever pursued, and thus be a lasting benefit to the trade generally. It was now busily engaged in opposing the Pharmacy Bill, which had been introduced into the House of Commons by Sir Michael Hicks-Beach, which, if carried, would have a detrimental effect upon the Pharmaceutical Society. As the Bill was now framed any young man might, after passing certain examinations in Ireland, return to this country and commence business as a chemist and druggist without paying anything, or only a small acknowledgment, to the Society. Petitions had been sent up against this Bill, and he read replies which had been received from the East Riding and borough members on the subject. Their respected friend Mr. Baynes was on the Council of the Pharmaceutical Society, and they must all admit that the local society, mainly through his instrumentality, had received great benefit at the hands of the Society. He concluded by thanking them for the compliment they had paid him by electing him for the fourth year the local honorary secretary of the Society.

The President, in proposing the toast of the evening, alluded to the invaluable services which Mr. Baynes had rendered, not only to the Hull Chemists' Association, but to the trade generally. In the name of the Association and the trade, he asked Mr. Baynes' acceptance of a humble tribute of their gratitude and esteem. It might have assumed the shape of a more valuable gift, but after consideration they felt that rather than adopt the stereotype form of presenting a piece of plate, as conveying their individual esteem and good wishes, it would be preferable to offer Mr. Baynes a presentation from that society which he had so nobly aided.

The testimonial consisted of a handsomely illuminated address, in a gilt frame, the margin being adorned by Mr. Baynes' monogram, and some ancient trade marks, beautifully executed in gold and colours. The text was as follows:—"Hull Chemists' Association. At a meeting of the above association, held at the Cross Keys Hotel, on the 9th of March, 1875, the president, Mr. Anthony Smith, in the chair, the following resolution was proposed by Mr. Staning, and seconded by the vice-president (Mr. Myers), and carried unanimously:—"That the best thanks of this association are hereby presented to James Baynes, Esq., for his untiring exertions and valuable advice during the long period he has deservedly held so prominent a position in the trade of the town. The association further tender their best thanks to him for the faithful advocacy of their interests, and those of the trade generally, in the honourable position of member of the Pharmaceutical Council of Great Britain. The association desires to acknowledge with gratitude the many obligations they are under for the ready and willing manner in which he has, at all times, at much personal inconvenience, placed his abilities and energies at their disposal, and pray that the Great Architect of the Universe may bless him with health and strength to prolong his efforts for the good and welfare of his brother chemists."

Mr. Baynes, on rising to acknowledge the compliment paid him, was received with hearty applause. He said it often happened that in cases of this kind one individual carried off the honours which, in fairness, belonged to others; and he felt that was the case now with him. He dared not arrogate to himself anything approaching the terms in which they had chosen to express their recognition of his services; for in respect to earnestness and heartiness he could point to gentlemen who, in their day, had done as much for the trade as he had done. On one ground, perhaps, he might, without egotism, accept that testimonial as true, and that was simply as to length of service. He had from time to time during the last 35 years had occasion to use his energies in promoting that which he believed to be for the best interests of the trade. In 1839 the Medical Council were about making a raid upon the chemists, and he felt that had they succeeded in carrying out their intentions they would have sunk to the low condition of the ordinary trader—that they would have found themselves in the condition of the so-called chemists of Ireland, a mixture of the general dealer and something lower. Then, led on by such men as Jacob Bell, Charles John Payne, William Allen, and others, an association was formed simply as a trade protection society. They felt their interests were at stake; and out of that effort, he was happy to say, grew the Pharmaceutical Society, the beneficial results of which were patent to all present. During some twenty-five years he filled the office of local secretary, and in the early part of that time there was occasionally some hard work to do. Now, he thought, the trade, although in serious difficulty in many respects, was, after all, rising in status; and though he knew that would not earn them much bread and butter, still it was most satisfactory to all interested in the trade. They had been driven by Government either to accept a governing body elected by themselves, or the Medical Council, who would have been hard taskmasters indeed. Coming to more local matters, he for many years regretted that they had no local association, such as they now possessed, upon which they could fall back in case of need. They seemed to be a rope of sand; and though they had given him credit for many virtues, he never had the courage to try and form another society. He came in after the formation of the Hull Chemists' Association, and he thought he might say that during the time that had elapsed since its establishment, it had done a good work, in which he was sure others had taken a larger and more onerous share. They had often paid him the compliment of asking his advice, and that he had always honestly and faithfully rendered with a single eye to the advantage of the trade. Although, personally, he was not favourably disposed to testimonials, yet he regarded this as something more than an expression of dry thanks. They had thought fit to clothe their thanks in terms which he should long remember; and he had much rather receive such a token than one of greater intrinsic value. If such expressions were recorded on a simple sheet of paper they would be most acceptable, but placed as they had been on this beautiful work of art, he should ever remember that they conveyed very much more than appeared on the face of it.

Mr. Gates then proposed "The Health of the President," the toast being cordially received and acknowledged by Mr. Anthony Smith.

Mr. Oldham gave "The Healths of the Visitors," associating with it the name of Mr. H. J. Amphlett, who responded.

Mr. Baynes then proposed "The Healths of the Vice-President, Secretary, and Committee of the Hull Chemists' Association," the toast being acknowledged by Mr. George Myers, vice-president; Mr. C. B. Bell, secretary; and Mr. Oldham, on behalf of the committee.

The Pharmaceutical Journal.

SATURDAY, JUNE 12, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PHARMACY ACT (IRELAND) BILL.

A FURTHER postponement of the second reading of the Irish Pharmacy Bill until Monday, the 14th of June, is all the parliamentary progress we have to report as having taken place in connection with this measure since our last issue. There has been, however, no diminution of the activity displayed throughout the pharmaceutical community in forwarding to Parliament petitions against the proposed Bill. Up to the end of last week no less than 124 petitions had been presented, bearing the signatures of 1405 pharmaceutical chemists and chemists and druggists. Since that time, and up to Wednesday, 28 more petitions had been presented against the Bill, besides the petition of the Pharmaceutical Society.

Meanwhile there has been only a single petition presented in favour of the Bill, and, strange to say, this one has been sent by the King and Queen's College of Physicians in Ireland. Another instance is thus afforded of the singular inconsistency that has characterized the proceedings of our Irish friends in regard to pharmaceutical legislation. So far back as the time when the Pharmacy Act of 1868 was before Parliament, the same College of Physicians exerted its influence to bring about the extension of that Act to Ireland, and a circular was issued by the Registrar setting forth the grounds for desiring that the Bill should be altered so as to apply to Ireland as well as to England and Scotland. This circular pointed out the inconveniences resulting from the altered procedure of the Apothecaries' Company in regard to the granting of certificates "to open shop for the retail of medicine, and to practise the art and mystery of an apothecary," and from the innovation of requiring a four years' curriculum, comprising medical studies. It also showed that the want of compounding and dispensing establishments in Ireland, then universally complained of and yearly increasing under the existing state of the law and action of the Apothecaries' Company, might be remedied by one of two courses, either by the Apothecaries' Company granting, as formerly, its certificate on the condition required by the Act, viz., that the person applying for the certificate shall satisfy the Court of Directors as to his "knowledge of the business," or by the Bill (Pharmacy Act, 1868) then before Parliament being extended to Ireland, so as to supply what had become a very serious want, and at the same time to protect the public from the danger of ignorant persons compounding and dispensing medicines.

This circular then went on to state:—

"Either course would attain the desired end; but as the tendency of medical legislation in the several Medical Acts *is to assimilate the laws in England and Ireland*, and as *one Pharmacopœia or Formulary for compounding medicine*, '*The British Pharmacopœia*' has been substituted for the three—English, Irish, and Scotch—previously in force; it would seem the more desirable course to make the qualification the same for opening shop for the retail of medicine and compounding prescriptions in the three ocuntries.

"The inhabitants of the three countries will then have the same facilities for obtaining medicine, and having prescriptions compounded, and the same security against mistakes and unskilfulness in compounding, while the same reciprocity of rights which has been established by the Medical Acts for the three countries in regard to the practice of medicine and surgery will then be extended to pharmacy, permitting the apothecary or chemist to open shop indifferently in the three countries, provided he is properly qualified.

"LOMBE ATTHILL, M.D.,
"*Fellow and Registrar.*

"*College Hall, June* 15, 1868."

In the early part of last year, a Bill to amend the practice of pharmacy in Ireland was drawn up by the College of Physicians, and printed and circulated together with some explanatory observations.* Not long afterwards this very Bill, of which the sum and substance was the extension of the Pharmacy Act of 1868 to Ireland, was introduced into Parliament† by MR. ERRINGTON, MR. BLENNERHASSETT, and MR. BUTT, and eventually it was referred to a Select Committee which, after taking evidence, reported against the Bill.

The only representative of the King and Queen's College of Physicians who appeared to give evidence in reference to the Bill proposed by that body was the President of the College, Sir DOMINIC CORRIGAN, who to the astonishment of every one declared that he did not approve of the Bill, and gave evidence against it, suggesting at the same time that there was a necessity for a separate Pharmaceutical Society in Ireland.

Since that time Sir DOMINIC's views appear to have developed themselves more fully, and he has appeared as the adviser of the Irish chemists and druggists, warning them not to have anything to do with existing pharmaceutical societies.‡ It seems now that he has also succeeded in converting to his own peculiar views the body over which he presides, and

* See *Pharm. Journ.* [3], vol. iv., pp. 839, 847.

† *Ibid.*, pp. 1039, 1048.

‡ See before, p. 687

we may assume that he has led the College of Physicians to manifest the inconsistency of appearing as a petitioner in favour of a Bill which proposes to do the very reverse of that which it had in so elaborate a manner argued was the proper thing to do for amending the practice of pharmacy in Ireland.

Not long since we were hopeful that there was still some agreement between ourselves and Sir Dominic Corrigan in reference to Irish pharmacy and agreeing with him in the opinion that if the ranks of pharmacists in Ireland were to be augmented it must be from the body of chemists and druggists, we looked forward to some appropriate action being taken, under his guidance, by the Chemists and Druggists' Association, and wished them all success in such an endeavour to follow the example that has been set by pharmacists on this side St. George's Channel. As yet, however, we have no intimation that such a course is in contemplation, but in place of it there seems to be only a disposition to declaim against the *régime* of the Apothecaries' Company, and to look to Government to establish and support an Irish Pharmaceutical Society which, if it is to possess the independence and stability so much talked of as desirable, can, we believe, attain that end only as the result of united and voluntary efforts.

THE YORKSHIRE COLLEGE OF SCIENCE.

Little more than twelve months ago the first meeting of donors to the Yorkshire College of Science was held at Leeds, to decide upon the constitution of the College and to elect a Council, and within the last few days that Council has issued the first Annual Report, in which it has been able to speak of the taking of temporary premises, the appointment of professors, and the completion of the first courses of lectures as accomplished facts. Such energy and promptitude, it must be admitted, augur well for the future of the young institution. They will be invaluable in educating the Yorkshire public to a proper appreciation of the advantages pertaining to the College, which, from the statement that the number of day students has hitherto been small, would appear, as in early history of other similar institutions, to be at present somewhat wanting. It is satisfactory to learn, however, that short courses of evening lectures have been given, which have been more successful.

Another item in the Report furnishes food for congratulation, as indicating how the Yorkshire College of Science and kindred institutions may assist in solving the dormant problem of providing for the scientific education of pharmacists in the provinces. The Council states that arrangements have been completed with the Council of the Leeds School of Medicine, by which the students of that institution will go through their course of chemistry and laboratory practice at the College. At least twenty medical students are expected to attend Professor Thorpe's courses under this arrangement. Surely, in a county which boasts of one-fourth of the whole number of pharmaceutical organizations in Great Britain, there ought not to be much difficulty in raising an equal contingent of pharmaceutical students.

The "formal inauguration"—*pace* Mr. Freeman—of the College will take place at the commencement of the second session, in October next, when His Grace the Duke of Devonshire will preside, and will be supported by many distinguished men interested in the welfare of the College.

THE TRANSPORT OF POISONS.

An American contemporary states that recently a vessel arrived at New York, containing a large quantity of fine table salt, stored in sacks in the hold, and about a hundred kegs of arsenic between decks. During rough weather on the voyage the cargo shifted, and some of the arsenic escaped from the kegs and was washed by the sea down into the hold amongst the salt. After a portion of the salt had been disposed of and removed, the captain remembered this, and began to speculate as to the possible nature of the mixture. An examination of the salt by Professor Doremus removed his doubts by showing that it contained a considerable proportion of arsenic. Fortunately, by promptly telegraphing to the purchasers, all danger of poisoning was averted. Notwithstanding that the underwriters are endeavouring to persuade the owners of the salt that the addition of arsenic has enhanced its commercial value, most consignors and consignees of articles of food will feel that there is something very objectionable in a system of packing and loading which would allow of their aggrandizement in this way.

CINCHONA AND JALAP IN JAMAICA.

The *Lancet* states that several hundred acres of land in Jamaica are now devoted to the cultivation of cinchona, and that there is a probability that in a few years the island will supply the European market with a large quantity of good bark. Efforts have also been made to grow the jalap plant, and the last crop of jalap is said to have amounted to three or four hundred pounds.

DRUGS AND DRINK IN MISSOURI.

The disposition manifested by drug sellers in certain parts of the United States to encourage an undue development of the sale of non-official alcoholic preparations in connection with their ordinary trade, appears, at last, to have attracted the attention of legislators. The *Pharmacal Gazette* states that in Missouri an Act has been passed which provides that no dealer in drugs and medicines shall, without taking out a licence, directly or indirectly *sell or give away* any intoxicating liquor in less quantity than a gallon, except for medicinal or sacramental purposes, under a penalty of from fifty to two hundred dollars. Notwithstanding the apparent comprehensiveness of the words italicized, our contemporary points out that there is nothing to prevent a druggist loaning a bottle of whisky and taking a dollar as collateral security.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

After protracted deliberation and discussion it was eventually decided that the Annual Botanical Ramble of the members of this Association should be from Elton to Stamford; Fotheringhay Castle, Bedford Purlieus, and Burghley House to be visited *en route.*

On May 17th the favoured few started by rail along the Nene Valley. The weather, contrary to usual experience, being very fine, and the country most unusually beautiful, some lovely prospects being obtained over the county of spires and squires, here well deserving the alliterative epithet.

The entrance to Castle Ashby, the scene of the first ramble, was passed and Wellingborough soon reached. Wollaston with its ubiquitous church was on the right, near to it being the earliest extant example of early English architecture, Strixton church. Then came the beautiful spire of Higham Ferrers, the native place of Archbishop Chichele, once a parliamentary borough, and still, though only of village dimensions, retaining municipal dignity. Then came in quick succession, Raunds, Stanwick, Ringstead, and Thrapston. Above the latter, the river was white with *Ranunculus fluitans*, and bordered in the greatest profusion with showy masses of *Caltha palustris;* the smaller brooks were filled with dense thickets of *Typha Arundo*, whose dried stems looked strangely out of character with the fresh and blooming vegetation by which they were surrounded. Then on by the lovely woods of Lilford, past quaint Barnwell embowered in chestnuts, hiding its ruinous old castle now covered with the rich yellow wall-flower, Oundle, with its magnificent spire, was reached, and passing by Cotterstock, in whose sylvan beauties Dryden wrote his fables, on by Tansor, whose brooks are choked with *Hottonia palustris*, Elton station was at length reached. From here the party walked across to Fotheringhay, finding *Orchis Morio* and *Carex glauca* in the fields, and *Verbascum Blattaria* and *Anthriscus vulgaris* on the walls, while the ditches furnished *Carex riparia* and *vulpina* in abundance. The splendid church of Fotheringhay was soon an object of admiration, it being one of the 15th century edifices, with handsome tower, surmounted by an octagonal lantern, which, with the high site, gives it a very imposing appearance. The interior is chiefly remarkable for containing two monuments erected by Elizabeth to Richard and Edward, dukes of York, who fell fighting, respectively at Agincourt and Wakefield. Some beautiful chestnut trees were examined, and the peculiarity of the relative length of stamens and pistil (as in the *Primula*) being reversed in different plants was noticed.

The site of the castle was then visited, and though the earthworks still remain but one fragment of masonry near the river is the only relic left of the castle which for so long a time held prisoner Mary, Queen of Scots. The moat furnished botanically *Ranunculus intermedius, Potamogeton natans* and *Iris Pseudacorus.* On the sides of the mound *Hyoscyamus* was soon found then came *Veronica serpyllifolia, hederifolia,* and *arvensis,* followed by *Papaver somniferum*, which was scattered all around. Then a shout hailed the discovery of *Ranunculus parviflorus*, whose tiny mutilated petals and tuberculated carpels were eagerly examined. The south side of the mound was blushing red with the *Erodium cicutarium*, and here was found the *Onopordon Acanthium,* and a seedling *Carduus eriophorus.* On returning through the village an old dame inquired if we had been gathering Queen Mary's thistle, alluding to *Onopordon*, which tradition says was brought to Fotheringhay by Mary's attendants.

Proceeding to Stamford by the old road, long disused for traffic, now covered with greensward, and bordered for some distance by the wood of Bedford Purlieus, in which *Allium ursinum* made a most pleasing contrast in colour to the *Scilla nutans, Lamium Galeobdolon* was also plentiful. By the roadside a great clump of *Belladonna* was found, and then the woods yielded quickly after *Luzula sylvatica, Aquilegia vulgaris,* the beautiful *Melica uniflora, Melampyrum pratense, Habenaria chlorantha,* and the rare (in Northamptonshire) *Euphorbia amygdaloides. Convallaria majalis* is also found plentifully in the Purlieus, but time did not permit going to its habitat. *Circæa lutetiana* was common, and the *Conium* and *Belladonna* also frequent.

Wittering Heath, now enclosed, was then crossed, and on its dry sandy soil a new set of plants was found, *Cerastium arvense, Origanum vulgare, Reseda lutea, Helianthemum vulgare* being met with in abundance. An old willow swamp contained the great tufts of *Carex paniculata,* while further on, nearly covered with *Tamus communis, Daphne laureola* and *Viburnum Lantana* were plentifully growing.

A hasty glance after the arrival at Stamford was given to the town before dinner, at which Mr. Hester presided, the vice-chair being filled by Mr. Druce. The usual loyal and local toasts having been drunk, but short time remained to see Burghley House, but a sharp run through the fine park and avenues brought the party to the magnificent pile of buildings forming Burghley House, and much pleasure was enjoyed in passing through the superb suite of rooms, filled as they are with objects of *vertu.* The portrait of the "Village Countess" was, of course, pointed out and Tennyson's charming ballad rehearsed, but *the* picture was one of the Saviour, by Carlo Dolci, its exquisite expression of divine love, compassion, and sorrow, well deserving it to be called the "gem of the house." The rooms occupied by Queen Elizabeth and Queen Victoria were also objects of interest, and the beautifully painted ceilings much admired.

But little time was left to get to the station, and the party were soon whirled homewards through the Welland Valley, passing on the right Kelton, celebrated for its stone quarries, and on the left Colley Weston, for its roofing slates. Rockingham Castle was quickly left behind, just one glimpse of Uppingham being obtained and then Market Harborough was reached; here the railway banks were covered with *Thlaspi arvense.* Then on by the valley through which that branch of the Nene which rises on Naseby Field flows. Northampton was reached by 8 p.m., after a very pleasant day, resulting in a few good finds, and in seeing in flower or fruit 147 species of plants.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, June 3, 1875. Professor Abel, F.R.S., etc., in the chair. After the usual business of the Society, numerous papers were read, the first of which was on "The Effects of Pressure and Cold upon the Gaseous Products of the Distillation of Carbonaceous Shales," by Mr. J. T. Coleman. He finds that 1000 cubic feet of the gas produced in such large quantities at shale oil works, when submitted to pressure, will give about one gallon of volatile hydrocarbons fit for improving the illuminating power of ordinary coal gas. 2. "On the Agricultural Chemistry of the Tea Plantations of India," by Dr. C. Brown, giving analyses of the ashes of tea and the effect of fertilizers on the growth of the plant. 3. "On the Structure and Composition of Certain Pseudomorphic Crystals having the Form of Orthoclass," by Mr. J. A. Phillips. 4 and 5. "Note on the Sulphates of Narceine and other Narceine Derivatives," and "On the Action of Organic Acids and their Anhydrides on the Natural Alkaloids, Part V.," both by Mr. G. H. Beckett and Dr. C. R. A. Wright. 6. "On the Action of Chlorine on Pyrogallol," by Dr. J. Stenhouse and Mr.

C. E. Groves, with an Appendix by Mr. Lewis on the crystalline forms of mairogallol, one of the products. 7. "On Nitro-alizarin," by Mr. W. H. Perkin, F.R.S., etc. This compound, obtained by the action of nitric acid on diacetyl-alizarin, dyes fabrics mordanted with alumina of an orange colour, whilst the amido-alizarin obtained from it by reduction gives a fine purple. 8. "On Some Metallic Derivatives of Coumarin," by Mr. R. Williamson. And 9. "On the Action of Dilute Mineral Acids on Bleaching Powder," by F. Kopfer. The next meeting, the last of the session, will take place on Thursday, June 17, when the following papers will be read:— 1. "On Nitrosyl Bromide," and "On Sulphur Bromide," by M. M. P. Muir. 2. "Notes on the Chemistry of Tartaric Acid and Citric Acid," by R. Warington. 3. "On the Action of Nitric Acid on Copper, Mercury, etc., especially in the presence of Metallic Nitrates," by J. J. Ackworth. 4. "Decomposition of Water by the Joint Action of Aluminium Bromide, Iodide or Chloride, including Instances of Reverse Action," by Dr. Gladstone and Mr. Tribe. 5. "On Achrematite, a new Arseniate of Lead," and 6. "New Reactions of Tungsten," by Professor Mallet. 7. "On the Action of Chlorine on Acetamide," by E. W. Prevost.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture VI.

Physical deterioration from Alcohol, continued. Influence on the vital organs. Mental phenomena induced by its use. Summary.

Towards the close of my last lecture I touched on the effects of alcohol upon the colloidal structures of the body, indicating that it is impossible for these structures to escape deterioration under its continued action. I must dwell for a few moments longer on this subject.

The parts which suffer most, at first, from alcohol, are those expansions in the animal body which the anatomists call the membranes. The membranes are colloidal structures, and every organ is enveloped in them. The skin is a membranous envelope; through the whole of the alimentary surface, from the lips downwards, and through the bronchial passages to their minutest ramifications, extends the mucous membrane; the lungs, the heart, the liver, the kidneys, are folded in delicate membranes which you can strip easily from these parts. If you take a portion of bone you will find it easy to strip off from it a membranous sheath or covering; if you open and examine a joint you will find both the head and the socket lined with membrane.

The whole of the intestines are enveloped in fine membrane, called *peritoneum.* All the muscles are enveloped in membranes, and the fasciculi or bundles and fibres of muscles have their membranous sheathing. The brain and spinal cord are enveloped in these membranes; one nearest to themselves, a pure vascular structure, a network of blood vessels; another, a thin serous structure; a third, a strong fibrous structure. The eyeball is a membrane of colloidal humours and membranes, and of nothing else. To complete the construction, the minute structures of the vital organs are enrolled in membranous matter.

It was held by the old anatomists that this membranous arrangement of the body is mainly mechanical. The parts and organs, according to their view, are supported and held in position by these membranous sheaths and pouches and coverings. Doubtless this is a portion of their usefulness, for in fact they do hold all the structures together in the most perfect order. But this is only a small part of their duties. The membranes are the filters of the body. In their absence there could be no building of structure, no solidification of tissue, no organic mechanism. Passive themselves, they nevertheless separate all structures into their respective positions and adaptations.

The animal receives from the vegetable world and from the earth the food and drink it requires for its sustenance and motion. It receives colloidal food for its muscles; combustible food for its motion; water for the solution of its various parts; salts for constructive and other physical purposes. They have all to be arranged in the body, and they are arranged by means of the membraneous envelopes. Through these membranes nothing can pass that is not for the time in a state of aqueous solution like water or soluble salts. Water passes freely through them, salts pass freely through them, but the constructive matter of the active parts that is colloidal does not pass; it is retained in them until it is chemically decomposed into the soluble type of matter. When we take for our food a portion of animal flesh, it is first resolved in digestion into a soluble fluid before it can be absorbed; in the blood it is resolved into the fluid colloidal condition; in the solids it is laid down within the membranes into new structure, and when it has played its part it is digested again, if I may so say, into a crystalloidal soluble substance ready to be carried away and replaced by addition of new matter, then it is dialysed or passed through the membranes into the blood, and is disposed of in the excretions.

See then what an all-important part these membranous structures play in the animal life. Upon their integrity all the silent work of the building up of the body depends. If these membranes are rendered too porous, and let out the colloidal fluids of the blood—the albumen for example—the body so circumstanced dies; dies as if it were slowly bled to death. If, on the contrary, they become condensed or thickened, or loaded with foreign material, then they fail to allow the natural fluids to pass through them. They fail to dialyse, and the result is either an accumulation of the fluid in a closed cavity, or contraction of the substance enclosed within the membrane, or a dryness of membrane in surfaces that ought to be freely lubricated and kept apart. In old age we see the effects of modification of membrane naturally induced; we see the fixed joint, the shrunken and feeble muscle, the dimmed eye, the deaf ear, the enfeebled nervous function.

It may possibly seem to some of you at first sight that I am leading away from the subject of the secondary action of alcohol. Not so. I am leading directly to it. Upon all these membranous structures alcohol exerts a direct perverting power of action. It produces in them a thickening, a shrinking, and an inactivity that reduces their functional power. That they may work rapidly and equally they require to be at all times charged with water to saturation. If into contact with them any agent is brought that deprives them of water, then is their work interfered with; they cease to separate the saline constituents properly, and if the evil that is thus started be allowed to continue, they contract upon their contained matter in whatever organ it may be situated, and condense it.

In brief, under the prolonged influence of alcohol those changes which take place from it in the blood corpuscles, and which have already been described, extend to the other organic parts, involving them in structural deteriorations, which are always dangerous, and are often ultimately fatal.

Preliminary Effects on Vital Functions.

I remarked in my last lecture that the slow or chronic effect of alcoholic drink upon the body was to induce a series of stages analogous in all respects, except in period of duration, to the process of acute poisoning by the same agent. In the first prolonged stage there occur phenomena of disease which are as characteristic of the agency when it is known as they are deceptive when the agency is not known.

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts.*

The ultimate changes that follow the use of alcohol by those who indulge in it, in what is too often considered a temperate degree, are actual local changes within one or other of the vital organs. But before such actual deterioration obtains there are usually other phenomena transitory in character yet unequivocal. I pointed out certain of these in the last lecture, but I did not specify them all.

In addition to that irritation of mind and suffering "of wounds without cause," to which I then drew attention, an extreme emotional derangement is often produced. The afflicted man—and I fear I must say woman also, for women are sometimes afflicted—the afflicted man under this primary prolonged influence of alcohol becomes nervous and excitable, ready at any moment to cry or to laugh, without valid reasons for either act. The emotional centres are alternately raised and depressed in function by the poison, but after a time the depression overcomes the exhilaration, and the impulse is to a maudlin sentimentality extending even to tears. The slightest anxieties are then exaggerated, and there is experienced at the same time an indecision and deficiency of self-confidence which is doubly perplexing. When an act is done, when a letter, for instance, or other piece of business has been finished and despatched, an uneasy feeling of distrust is felt that perhaps some mistake has been made, which distrust passes rapidly into a sentiment that the thing cannot be helped; it is bad luck, but it must take its chance. In various other directions this distrust shows itself, and the worst of all is, that the very doubt prompts the desire for another application for relief to the evil that is the cause of the burthen. A small dram more of the stimulant, not an overpowering draught that will cause quick and sure insensibility, but just a mouthful, that is the remedy, and that is the certain promoter of the sorrow.

We know now, as surely as if we could see within the body, what is the condition of the organs of the person afflicted in the manner thus defined. We are conscious that the vessels of the brain, of the lungs, of the liver, of the kidneys, of the stomach are paralysed, and are injected to full distention with blood. Some of these parts have actually been seen under this state, and the fact of the red injected condition directly demonstrated.

Alcoholic Dyspepsia.

Of all the systems of organs that suffer under this sustained excitement and paralysis, two are injured most determinately, viz., the digestive and the nervous. The stomach, unable to produce in proper quantity the natural digestive fluid, and also unable to absorb the food which it may imperfectly digest, is in constant anxiety and irritation. It is oppressed with the sense of nausea; it is oppressed with the sense of emptiness and prostration; it is oppresed with a sense of distension; it is oppressed with a loathing for food; and it is teased with a craving for more drink. Thus there is engendered a permanent disorder which, for politeness' sake, is called dyspepsia, and for which different remedies are often sought but never found. Antibilious pills—whatever they may mean—Seidlitz powders, effervescing waters, and all that pharmacopœia of aids to further indigestion, in which the afflicted who nurse their own diseases so liberally and innocently indulge, are tried in vain. I do not strain a syllable when I state that the worst forms of confirmed indigestion originate in the practice that is here explained. By this practice all the functions are vitiated, the skin at one moment is flushed and perspiring, at the next is pale, cold, and clammy, and every other secreting structure is equally discomposed.

Nervous Derangements.

The nervous structures follow the stomach in the order of derangement, or, it may be, precede it. We have not yet traced out with sufficient care the conditions of the centres of the organic chain of nerves, but we know that they are reduced in power; and, in regard to those higher and reasoning centres, the brain and its subsidiary parts, the spinal cord and voluntary nerves, we are aware that they are supplied with blood through vessels weakened, and in a condition either of undue tension or undue relaxation. Moreover, the delicate membranes which envelop and immediately surround the nervous cords are acted upon more readily by the alcohol than the coarser membranous textures of other parts, and thus a combined arrangement of evils affects the nervous matter. The perverted condition of the nervous centres gives rise to many striking phenomena, extending from them to the nervous cords and to the organs of sense. The irregular supply of blood to the retina causes temporary disturbances of vision, with appearances before the eyes of those specks and small rounded semi-transparent discs, which are called by the learned *muscæ volitantes*. From the imperfect tension of the arteries, the blood which rushes through causes dilatation of them, and in the bony canals of the skull an impingement is made upon the bony structure. Vibrations which extend to the neighbouring organs of hearing are thus produced, giving rise to sounds of a murmuring, ringing, or humming character, according to the modification of the arterial tension.

The perverted condition of the membranous covering of the nerves gives rise to pressure within the sheath of the nerve, and to pain as a consequence. To the pain thus excited the term neuralgia is commonly applied, or tic; or if the large nerve running down the thigh be the seat of pain, "sciatica." Sometimes this pain is developed as a toothache. It is pain in nearly every instance, commencing at some point where a nerve is enclosed in a bony cavity, or where pressure is easily excited, as at the lower jaw bone, near the centre of the chin, or at the opening in front of the lower part of the ear, or at the opening over the eye-ball in the frontal bone.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Pharmacy Act (Ireland) Bill.

The second reading of this Bill has been postponed until Monday next, the 14th inst.

On Monday, June 7, Dr. Lyon Playfair gave notice that on Monday, June 14, he would ask the Chief Secretary for Ireland the following questions:—(1) How many Licentiates are there of the Apothecaries' Hall in Ireland who restrict themselves to pharmacy; that is, who do not at the same time practise medicine or surgery? (2) And is there any other class of chemists and druggists in Ireland who can legally dispense medicines according to prescriptions?

The following petitions against the Bill have been presented since Thursday, the 3rd inst.:—

From the Pharmaceutical Society of Great Britain.

Aylesbury	Mr. Nathaniel M. de Rothschild.
Bath	Major Nathaniel G. B. Bousfield.
Birkenhead	Mr. David MacIver.
Birmingham	Right Honourable John Bright.
Blackburn	Mr. William Edward Briggs.
Bolton	„ John Hick.
Bridgnorth	„ William Henry Forster.
Brighton	„ James Lloyd Ashbury.
Cardigan	„ Thomas Edward Lloyd.
Carlisle	Sir Wilfred Lawson.
Carmarthen	Mr. Charles William Nevill.
Chichester	Lord Henry G. C. G. Lennox.
Cirencester	Mr. Allen Alexander Bathurst.
Darlington	„ Edmund Backhouse.
Evesham	Colonel James Bourne.
Exeter	Mr. Arthur Mills.
Eye	Viscount Barrington.
Glasgow	Mr. George Anderson.
Great Grimsby	„ John Chapman.

Hanley ....Mr. Robert Heath.
Hitchin .... „ Abel Smith.
Huntingdon ....Sir John Burgess Karslake.
Launceston ....Mr. James Henry Deakin, jun.
Leeds.................... „ W. St. James Wheelhouse.
Leith .... „ Donald R. Macgregor.
London ....Alderman Sir James C. Lawrence.
Maldon ....Mr. George M. W. Sandford.
Newport (Mon.) ... „ Thomas Cordes.
Nottingham .... „ Bernhard Samuelson.
Sheerness .... „ Edward Leigh Pemberton.
Sheffield .... „ Anthony John Mundella.
Stirling .... „ H. Campbell Bannerman.
Stroud .... „ Alfred John Stanton.
Truro....................Lt.-Col. Sir J. M. Hogg, K.C B.
Ulverston ....Captain the Hon. F. A. Stanley.

Petitions were also presented from the following places:—

Aberystwith.	Eastbourne.
Bradford.	Torquay.
Coventry.	Ursham.
Dorchester.	

The Sale of Food and Drugs Bill.

This Bill was read a second time in the House of Lords on Monday last. In moving the second reading the Duke of Richmond said the Bill had been introduced into the House of Commons in consequence of the failure of previous legislation on the subject, and was based on the report of a Select Committee. That Committee had reported that considerable hardship had resulted to retailers in consequence of their having been punished for adulteration over which they had had no control. It recommended that the defendant in proceedings for selling adulterated articles should be allowed to give evidence, and the Bill gave effect to that important recommendation. The Bill made it an offence to mix any injurious foreign substance or liquid with any article sold as food or a drug. For the first offence a penalty of 50*l.* might be imposed, and for a second six months' imprisonment. The adulteration must be injurious in order to subject the defendant to such consequences. The mixing with an article of any foreign article merely for the purpose of rendering it more palatable or portable was not to be an offence, provided the person selling it labelled the adulteration on the article to be sold. Under the existing law there was no penalty for abstraction from the ingredients of which an article was composed. Thus it was no offence to abstract the cream from milk or to abstract essential oils. The Bill dealt with abstractions as well as with additions. It contained provision that the seller of the adulterated article might plead in court that it had been warranted to him as genuine, and it gave him power to proceed against the wholesale dealer. As regarded analysts, it enabled small districts to combine together so as to employ an analyst to act for them jointly. It provided that no one engaged in retail trade should be appointed an analyst, and it provided that when proceedings were about to be instituted, one portion of the article should be left with the intended defendant, that another should be given to the prosecutor, and that a third should be handed to the analyst. Both the defendant and his wife might give evidence ; and if the skill of the local analyst were called in question there might be a reference to Somerset House for the purpose of further analysis.

In the discussion which followed—

The Earl of Morley ventured to think that the Act of 1872 had proved of considerable benefit to the community. At the same time, he agreed with the Select Committee that it was desirable to protect retail dealers from vexatious prosecutions and from any possible unfairness in respect of analysis and in respect of proceedings which might follow the making of the analysis. There were certain expressions in clauses of this Bill which would require careful consideration in committee. He thought the word "knowingly" would cause great difficulty in the working of the Bill, and that the words "prejudice of the purchaser" would also cause embarrassment. The proposal to enable districts to join together for the appointment of an analyst he regarded as a very desirable one.

Lord Redesdale suggested that in Clause 7 it would be well to introduce words requiring the seller to state what it was the article was mixed with, and what was the percentage of the foreign ingredient.

The Sale of Mixed Cocoas.

In the Court of Common Pleas on Monday, the 7th inst., a case came before Mr. Justice Brett and Mr. Justice Denman, which had been stated by the Justices for the division of Spalding, Lincolnshire, for the opinion of the Court upon the Adulteration of Food, etc., Act, 35 and 36 Vict. c. 74, sections 2 and 3.

The appellant, who was a grocer at Spalding, upon being asked for a quarter of a pound of cocoa, delivered to the respondent an ordinary packet of Epps's cocoa, without making any verbal statement as to its contents. Upon the face of the packet were the words "prepared cocoa, for ingredients see the other side," and upon the back, "cocoa contains a bland oil which is pre-eminent as a vitalizing substance; to render the oil soluble and easy of digestion, it needs to be combined with just so much loaf sugar and West India arrowroot as will effect its perfect incorporation. In the preparation of the cocoa contained in this packet we guarantee that no other ingredients than those mentioned are used." The respondent, who bought the cocoa for the purpose, then had it analysed, and it was certified to contain "40 per cent. of cocoa, 44 per cent. of sugar, and 16 per cent. of starch." The information, under section 2 of the Act, charged the respondent with having sold as unadulterated cocoa, cocoa that was adulterated. The Justices convicted the defendant and fined him 40*s.*, and stated this case for the opinion of the Court upon the validity of such conviction.

The Court quashed the conviction, holding that, assuming the cocoa could be properly said to be "adulterated cocoa," still it had not been sold as unadulterated. The mere handing of the packet did not constitute a complete sale, passing the property into the purchaser. It was open to him if it did not correspond with what he had asked for to reject it. And here there was a printed statement which immediately brought to the notice of the purchaser the fact that the article was a preparation of cocoa and the ingredients of which it was composed. Therefore, whether it was true or not, as had been stated, that the mixture of some such ingredients was necessary to make pure cocoa edible, this cocoa could not be said to have been sold as unadulterated.

Death Through an Overdose of Epsom Salts.

On Wednesday, May 26, an inquest was held at Rainham, by Mr. T. Hills, touching the death of Sarah Ann Daniel, aged 27 years, who resided at Station Lane, Rainham. It appeared from the evidence of the mother of the deceased, that early on Tuesday morning she complained of feeling very ill and being numbed all over. She said she had taken two packets of salts, as she had the headache. A doctor was sent for, but before medical aid could be obtained she expired. Deceased told her mother that she bought the salts of a person named Jacobs. Dr. Penfold said he procured two samples of salts, containing one ounce in each packet, at the shop of Mrs. Jacobs ; he examined them, and found them to be simply Epsom salts ; they came out of the same box as those supplied to Mrs. Daniel. He made a *post-mortem* examination which proved that the stomach was filled with a solution of Epsom salts ; the brain was healthy, and from examination of the organs, he pronounced the death of the young woman to have been from syncope, owing to strong doses of an aperient medicine, viz., Epsom salts, having been taken. The jury immediately returned a verdict in accordance with the medical testimony.—*Rochester and Chatham Journal.*

Poisoning by a Vermin Killer.

On Friday, May 28th, Mr. Moore, coroner, held an inquest at Warwick respecting the death of Louisa Popple, aged 17, who had committed suicide by taking poison. After evidence had been given as to the circumstances attending the death, and a statement of the deceased as to the purchase of the poison—

Mr. Charles Williams, chemist and druggist, Warwick, said the deceased, whose mother he knew also, had on several occasions been a customer at his shop. On the afternoon of Tuesday, the 25th May, between three and four o'clock, deceased came to the shop and asked for a packet of mice-poison, telling witness it was for her mother, who wanted to poison some mice. He supplied deceased with a threepenny packet of Battle's Vermin Killer. He was not supposed to know what were the contents of the packet, which was sold to him; but he told deceased to caution her mother that the packet contained poison. There was also a printed caution on the inside of the packet. Deceased had not, to his knowledge, ever asked for packets of this nature before.

The superintendent of the police said he could not obtain the vermin killer at other chemists' shops without bringing a witness or signing a book, but Mr. Williams said it was not obligatory to do either. He was aware that some chemists had adopted the practice. Every tradesman who sold the "killer" was obliged, however, to put his name on the packets.

Medical evidence was given that death had been caused by strychnine and the jury returned a verdict that deceased had poisoned herself whilst in an unsound state of mind.—*Leamington Advertiser.*

Poisoning by Laudanum.

On Friday, May 28th, at Leamington, an adjourned inquiry was held by Mr. W. S. Poole, coroner, into the circumstances connected with the death of George Townsend, aged 21, who had been found in bed at his lodgings in a comatose state and died two hours afterwards. A labelled bottle which had contained laudanum was found near him, and some letters which showed that he had an intention to commit suicide at the time of writing them.

Mr. Thomas Loveitt, chemist and druggist, of Coventry, identified the empty bottle found in the deceased's bedroom as one in which he had supplied two ounces of laudanum to a young man, apparently about 21 years of age, who, in answer to a question, said that he was suffering from nervousness, and had been ordered by his doctor to take from five to ten drops, in order to procure sleep. He told the young man to be sure not to take more than ten drops, as that was equal to half a grain of solid opium, and cautioned him that he might become addicted to the habit of taking laudanum. The man did not appear at all depressed, but was very chatty, and was in the shop from five to ten minutes.

The Coroner: This bottle would be nearly full. That would be quite sufficient to poison a man?

Mr. Loveitt said it would be quite sufficient to poison a great many men. He told the man that ten drops were quite enough for him, and he replied, "You are very particular," to which witness rejoined that he was obliged to be in such cases. When told that it would be 6*d.* an ounce, he said he had paid 8*d.* before.

The foreman observed that caution ought to be exercised in selling poison.

Mr. Loveitt said he should not sell laudanum to any person where his suspicions were in any way aroused, but the young man in the present instance seemed perfectly collected, and obtained it by making a false representation—that he had been ordered by his doctor to take it for sleeplessness.

The Coroner said it was quite impossible to prevent persons obtaining poison by Act of Parliament, and laudanum was not one of those included in the schedule of the Pharmacy Act, where it was necessary that the purchasor should be known to the vendor, or be introduced by a mutual friend, and had to sign a book.

The foreman having asked Mr. S. U. Jones, pharmaceutical chemist of Leamington, and local secretary of the Pharmaceutical Society, who happened to be in the room where the inquiry was being held, whether he would sell laudanum to a stranger?

Mr. Jones said it would depend upon circumstances, that laudanum was frequently used in large quantities externally as an anodyne, and if a person were to come to him and state that his medical man had directed it to be used in that way, he should have no hesitation in supplying two ounces, as half an ounce was frequently used for one application. He explained also that laudanum was not one of the poisons in the first schedule of the Pharmacy Act, 1868, so that it was not necessary for the purchaser to bring a witness or sign a book.

Mr. J. Fenn Clark said that, since the previous inquiry, he had analysed the contents of the stomach of the deceased; and every test, one alone excepted, indicated the presence of opium.

The jury returned a verdict that the deceased committed suicide by taking laudanum, but that there was no satisfactory evidence as to the state of his mind when he did so.—*Leamington Advertiser.*

Manual of Public Health for Ireland. By T. W. Grimshaw, M.A, M.D., J. Emerson Reynolds, F.C.S., Robert O'B. Furlong, M.A., Barrister-at-Law, and J. W. Moore, M.D. Dublin: Fannin and Co. 1875.

A Manual of Hygiene, Public and Private, and Compendium of Sanitary Laws. By C. A. Cameron, Ph.D., M.D., etc. With 35 illustrations. Dublin: Hodges, Foster and Co. London: Baillière and Co. 1874.

Public hygiene or preventive medicine is now a recognized branch of professional study. It is not a new science, but a new method of using carefully ascertained facts which bear upon the health of the masses, and the application of which is rendered practicable only by legislative enactment.

The prevention of disease is essentially the function of the physician who is conversant with the causes which produce it; but although the study of prophylactic measures against the ingress and aggravation of disease has, from time immemorial, been included in the regular medical curriculum, it has never been regarded as being of more importance than a subsidiary matter in the ordinary schemes of curative treatment.

The medical practitioner is daily consulted as to what will avert the complaints which his patients conceive to be impending, or have reasonable fears will be their lot to inherit by entail; and he as frequently ventures to advise with the view of checking some weak indulgence which may be a folly of fashion, or of strenuously putting down some growing passion which may eventually attain to the magnitude of unconquerable vice. But beyond offering his advice, which is often as ineffective as it is gratuitous, the physician has neither the means nor the right to interfere with the liberty of action of his patients. "In all such cases," as Mr. J. S. Mill truly observes, "there should be perfect freedom, legal and social, to do the action and stand the consequences." Imprudence, therefore, in the management of personal affairs is not a subject for legislation. But the case is entirely altered when the conduct of one becomes hurtful to another. The omission or commission of some act on the part of one individual, either from motives of personal interest, or from sheer ignorance, may involve the well-being of the whole community. Under these circumstances it becomes necessary for authority to step in and correct the action of misguided liberty.

A man blunted in his perceptions may fail to appreciate the æsthetics of filth and putrefaction, and so create not only a simple nuisance, but an active source of disease to his luckless neighbours, without perhaps being aware that he has committed any great evil. Or a butcher may endeavour to make the best of a bad bargain by inducing the poor and ignorant to buy tainted meat at a very cheap price. All such palpable nuisances, which are readily recognized by the most ordinary experience as the causes of disease, it is the duty of inspectors of nuisances to detect and remove, under the orders of the district sanitary authority.

But there are a host of subtle and insidious causes of disease arising from climate, physical geography and general topographical conditions, which require the most careful investigation of a special and technical kind for their detection and removal; and those who devote themselves to the study of public hygiene stand in need of a far more extended knowledge of science than a mere physician or surgeon who occupies himself solely with the curative treatment of disease.

Sanitary science embraces a very wide range of subjects; and health officers can only be efficient and competent for their work when they combine in themselves the knowledge—more or less profound—of the physicist, the chemist, the geologist, and the statistician, besides that of the practical physician.

It would be preposterous, therefore, to expect that a manual of three or four hundred pages should comprise an exhaustive treatment of these several branches of knowledge. It is just as absurd as it would be to expect that a manual of the practice of medicine should comprise a complete course of anatomy and botany, chemistry and physiology, therapeutics and pathology. But as the 'Medical Manual' argues the previous knowledge of these subjects, and is intended only as a guide to clinical study and medical practice, so the manuals on hygiene take for granted a certain amount of practical knowledge of the sciences, and a certain degree of dexterity in the use of the microscope, and of skill in chemical manipulation.

The demand for books on hygiene is of a threefold nature: (1) by the student, for an accurate hand-book on the elements of sanitation; (2) by the busy health officer for a trustworthy manual of reference; and (3) by the public analyst for a manual of the simplest and most reliable methods for conducting special operations. It would be too much to expect that any one book should fully satisfy this threefold demand. But it is not too much to hope that each description of inquirer will have all he can possibly need from the hands of those most competent to supply it.

Microscopy and analytical chemistry cannot, however, be learnt from books, but only in the laboratory; and the public analyst must already be something of a manipulator before he can honestly enter upon the duties of his office, or even avail himself of the particular methods described in works on hygiene for detecting adulterations or impurities in food, water, milk, etc.

On detection of a fraudulent adulteration, as certified to by the public analyst, the adulterator becomes liable to a fine; and as the analyst's report is received without question as evidence in court, the conviction and punishment of the accused will be just or unjust, according to the technical skill or bungling ignorance of the analyst.

We mention this in order to prevent any disappointment to those who aspire to become health officers and public analysts, and who fancy that the mere reading of a manual will sufficiently qualify them to meet all cases that might arise in the performance of their responsible duties.

Wilson's 'Handbook'—the first mentioned in the list at the head of this article—from its systematic arrangement and general scientific accuracy is eminently suited to the requirements of senior medical students and junior practitioners. The opening chapter is a condensed summary of judiciously selected facts of great importance on hereditary influence, the causes of deterioration and preventible disease, and serves as a proper introduction to the subjects which immediately follow. In chapter 2 is briefly considered the functions and constituents, nutritive values, and examination of different articles of food, together with the effects of insufficient or unwholesome food on public health. Chapters 3, 4, and 5 are devoted to air, its impurities, and their effects on public health; to the methods employed for its chemical and microscopic examination, and to ventilation. Chapters 6 and 7 treat of water, as to its supply, chemical examination and purification. Chapters 8 and 9 of dwellings and hospitals. Chapters 10, 11, and 12 of the removal, purification, and utilization of sewage. Chapter 13 treats of preventive measures and disinfection; and chapter 14 of the duties of medical officers of health. This, we repeat, is *the* text-book on hygiene for students.

The 'Manual for Health Officers,' by the late Dr. Edward Smith, consists for the most part of extracts from the various public Acts bearing upon sanitation, and may, on this account, be found to be useful. There are fifty-three tables of curious, valuable, and interesting statistics spread through the volume. But the scientific portion of this manual, or what professes to be such is not altogether very accurate or trustworthy.

The 'Manual of Public Health,' edited by Mr. Ernest Hart, is a more practical work, and intended for the use of local authorities as well as medical officers of health. It is divided into three separate parts,—legal, medical, and chemical,—written by three gentlemen severally experienced in each of the branches of knowledge involved. In the first part, Mr. Michael (barrister-at-law) points out the nature and extent of the powers conferred, and the responsibility imposed upon the various authorities and officers immediately concerned with the working and carrying out of the provisions of the Sanitary Acts. Annexed to this part are three indices, one to the statutes pertaining to public health, the second to the powers, and the third to penalties under the Acts; all of which are conveniently arranged for reference.

The second or medical part is in seven chapters which deal with questions more or less immediately connected with the functions of the health officer. It is more in the form of a commentary on the Sanitary Laws, interspersed with practical advice, and is written by Dr. Corfield, Professor of Hygiene in University College. The third and last part, written by Mr. Wanklyn, describes the methods and processes for the chemical examination of water, air, milk, wine, etc., with a few concluding sensible remarks on disinfection. The execution of this part is satisfactory, as might reasonably be expected from the author. We venture to suggest to the able and accomplished editor of this manual, that an index to the whole work would be a decided improvement in the second edition, and considerably enhance its usefulness.

The book that stands next for notice is the 'Manual of

Public Health for Ireland,' the conjoint work of two physicians,—who are also diplomates in state medicine of Trinity College, Dublin,—a barrister, and a chemist (Professor Emerson Reynolds).

Irish dispensary medical officers are appointed *ex officio* sanitary officers by section 10 of "The Public Health (Ireland) Act, 1874," and suddenly find themselves entrusted with the performance of duties which are both responsible and novel. The compilation of this manual was undertaken to meet their requirements, and we have no hesitation in pronouncing it a successful achievement. It will be referred to both as an educator and a guide in matters with which it deals, by those for whom it is especially intended. It is accurate and explanatory as far as it goes, and both health officer and medical student will find in it much useful information about statistics and meteorology, which they would seek for in vain in most manuals on hygiene.

Dr. Cameron's manual, the last in our list, is by far the most comprehensive work on hygiene which we have examined. It is professedly intended for the purposes of the Irish health officer, but it will be consulted by all earnest inquirers who desire a fuller account of the facts and discoveries which have contributed towards the establishment of the science of sanitation. The author seems to have spared no labour to render the book a thoroughly trustworthy manual of reference; and the industry with which he has collected his data, and the judgment and ability which he has exercised in the selection of the most readily available scientific methods, are conspicuous in almost every page of it. Dr. Cameron's 'Manual of Hygiene' will be found useful to both professional and non-professional readers, to the student as well as to the expert.

Obituary.

Notice has been received of the death of the following:—

On the 10th March, 1875, Mr. Thomas Davys Manning, Pharmaceutical Chemist, of Yeovil, aged 78. Mr. Manning had been a Member of the Pharmaceutical Society since 1869.

On the 9th May, 1875, Mr. John Hogan Barnes, Chemist and Druggist of Liverpool, aged 40.

On the 16th May, 1875, Mr. William Cameron, Pharmaceutical Chemist, of Kelso, aged 43. Mr. Cameron had been a Member of the Pharmaceutical Society, since 1865.

On the 26th May, 1875, Mr. John Wyman, Pharmaceutical Chemist, of Fore Street, London, aged 66. Mr. Wyman had been a Member of the Pharmaceutical Society since 1842.

On the 28th May, 1875, Mr. Ralph Caldwell Crafton, Pharmaceutical Chemist, of Croydon, aged 79. Mr. Crafton had been a Member of the Pharmaceutical Society since 1841.

On the 30th May, 1875, Mr. James Jackson, Chemist and Druggist, of Heywood, Lancashire, aged 46.

On the 2nd June, 1875, Mr. Frederick Curtis, Pharmaceutical Chemist, of Baker Street, London. Mr. Curtis had been a Member of the Pharmaceutical Society since 1853.

Correspondence.

THE INTERNATIONAL MEDICAL CONGRESS.

Sir,—In September of this year an International Medical Congress will take place in Brussels, the programme of which has already been published, and was referred to in the *Pharmaceutical Journal* last week. Medical congresses, as a rule, possess little to interest pharmacists, but the one before us is in this respect somewhat exceptional, and appears to me to merit a further notice in a Journal devoted to pharmacy. The subject matter of the 8th section is "Pharmacology," and the first question for discussion—"Faut-il étendre l'emploi médical des principes immédiats chimiquement définis et en multiplier les préparations dans les pharmacopées.' Rapporteur, M. Van Bastelaer, membre de la Commission Médicale du Hainault, pharmacien à Charleroi." The fact that a subject for discussion at a medical congress should be referred to a pharmacien is something new to British pharmacists, and deserves recognition. The future may be casting its shadows forward, and the sentiment uttered by one of the medical profession at our annual dinner may be nearer its realization than we imagine, "and as sure as the suns progress, your ultimate destiny is to form a living, integral, harmonious part of this great profession which exists only to bring forward the time which its own poet foretold in his inimitable lines—

"Ultima Cumæi venit jam carminis ætas,
Magnus, ab integro sæclorum nascitur ordo."

Surely this might be taken as an indication that "there's a good time coming," but in Great Britain I fear that we must "wait a little longer."

THOMAS GREENISH.

THE SALE OF VERMIN KILLERS.

Sir,—In the "Parliamentary and Law Proceedings" section of the Journal for May 29th and June 5th I see no notice taken of a coroner's inquest held on the body of a young girl who committed suicide, near Warwick, by taking Battle's Vermin Killer, supplied to her by a chemist in Warwick, who appeared as a witness at the inquest. How is it that a highly respectable firm in Wolverhampton was convicted and fined (together with expenses) £3 1s. only a few weeks ago, and this chemist is allowed to sell such deadly poison without conforming to the law on the sale of poisons? The difference between the two firms seems to be that one neglected to get the purchaser's address, whilst the other neither put name, address, nor purpose in the registration book. If it be true as stated by the seller at the inquest, that "we are not supposed to know what is contained in Battle's Vermin Killer" (I speak from the report in the *Chronicle* and *Advertiser*) and this is admitted to be sufficient guarantee that we may sell that deadly poison without taking any notice of the Sale of Poisons Act, then I think it becomes Mr. Cross's duty to reimburse Messrs. Reade and Co., of Wolverhampton, of the money mulct in fine and expenses. I should like your opinion on the matter in next issue.

A. P. S.

[*** Our correspondent will find a report of the case at p. 1001. Prior to the receipt of his letter no report had reached us. With respect to the question asked, we are unable to explain why there has been no prosecution in a case where there has been an evident infringement of the Act. The presence of strychnine in the preparation referred to is, we think, too notorious to admit of being ignored with safety.—ED. PH. J.]

THE DRUGGING OF ANIMALS BILL.

Sir,—Whether or not Sir J. Astley's "Drugging of Animals Bill" be more stringent than necessary, it is highly requisite that some restriction should be put upon the sale of nitrous acid, muriate of antimony, sulphate of iron, etc., to those agricultural servants who look after their masters' horses, and who have now no difficulty in getting six or eight ounces of any of the articles in Part 2 as published in the Journal. These drugs are obtained sometimes under the plea that they are wanted for "foot rot," but in reality are got to give to their horses for the purpose of "fining their coats," or as a "tonic," without their even knowing the powerful effect which these articles must exercise on the stomach. Many a farmer has been astonished at the mysterious way in which his draught horses have died. At one time waggoners were all anxious for "arsenic," but since the difficulty of obtaining it, the run has been upon the drugs enumerated in Part 2 of Sir J. Astley's Bill. For my part, I should like to see a greater check set upon obtaining these mineral acids and metallic salts. Depend upon it if some of these waggoners have to sign their names for what they purchase, there would be some hesitation, and consequently less likelihood of valuable horses "wasting away."

FROM AN AGRICULTURAL COUNTY.

PHARMACEUTICAL TITLES.

Sir,—Mr. G. L. Huett in the last *Pharmaceutical Journal* asks what is the contraction for pharmaceutical chemist. I suppose he means to ask what letters he can put after his name to show that he has attained to the position of pharmaceutical chemist. I should think Ph.C. would answer his purpose very well, certainly not P.C., as that may mean not only "Privy Councillor," but also in some districts "Police Constable," with neither of which, I suppose he would wish to be confounded; the best letters would be F.P.S., were there such a title as "Fellow of the Pharmaceutical Society." Until there is I should advise him, if he wishes, to write a paper for the Pharmaceutical Conference, or publish a book, to obtain a fellowship in some society,—as the Linneau or Chemical, both open to chemists of talent and scientific attainments,—or obtain the University degree of Sc.B. or Sc.D., both I think granted by the London University. Until the Pharmaceutical Society elect fellows I conceive their examinations will not gain a position entitling a man to put letters after his name.

WILLIAM PENNEY.

High Street, Poole, June 7, 1875.

Sir,—Your last issue contains an inquiry as to the best mode of indicating to the public by the use of certain letters at the end of a man's name that he is a pharmaceutical chemist. The public really do not care about or understand the difference between a pharmaceutical chemist and a member of the Pharmaceutical Society. The latter may as legitimately use the letters "M.P.S." as the former "P.C.;" the use of the three letters giving an appearance of quite as much if not more importance than the use of the two. But will the use of either add to the importance of the person using them in the eyes of any except himself? I trow not. The desire of many persons to swell themselves out by adding a tail to their names makes them look truly ridiculous. If a pharmaceutical chemist may proclaim his trade by adding P.C. to his name, why may not a linen and woollen draper add to his, L.W.D.? There are extant at present such a multitude of new fangled titles of this kind that one is sorely puzzled to interpret them; just as were the inhabitants of a little market-town in which a quack doctor took up his residence, and who had his cards printed "Jno. C. Blank, Esq., S.S.B.K." By the aid of these mystic letters he passed for a wonderfully clever man, until in a fit of candour he admitted to a friend over a glass of wine that all that was meant was that his house had stone steps and a brass knocker. I know the following to be a fact:—A gingerbeer maker went down to a watering place and took lodgings. Great was the astonishment of his landlady on receiving his letters to find them addressed to John Smith, Esq., M.P. On her expressing to him the pleasure she felt in entertaining a member of Parliament, he candidly assured her that he was not one, but was simply a "Maker of Pop."

These remarks are not intended to condemn the legitimate use of titles indicating that the user is a fellow of one of the well-known learned or scientific societies recognized as such by the general public.

AN OLD CHEMIST AND DRUGGIST.

A MODE OF MAKING SUPPOSITORIES, PESSARIES, ETC.

Sir,—While the above subject is on the carpet perhaps I may be allowed to write a few words upon a method of making those troublesome articles which often take up so much time and patience, and then do not turn out as well as expected.

As I have had some little experience in making suppositories and have tried various methods, including Mr. Ellis's, and the proposed improvement upon his by the use of waxed paper, I think I may venture to lay before your readers a very simple and cleanly plan which I now always adopt.

Take a piece of ordinary firewood and cut one end of it into the usual shape of a suppository, which figure can, of course, be modified according to the size required. Next cut pieces of tin foil about two inches square, and taking hold of one corner fold it over the mould, then with the fleshy part of thumb and forefinger gently smooth the foil round the mould and with a sharp knife run round the top, then insert the mould with the foil on it in the neck of a small phial, and on giving the wooden handle a slight twist and gentle pull the tin-foil mould will be left in the neck ready to receive the mass in the condition which is generally used for metal moulds.

The advantages which this method has will be apparent to all, viz.:—

(1) Cleanliness. The superiority of sticking the moulds into damp sand, whereby very often the sand becomes part of the suppository, and thus instead of having its ordinary effect, the medicine becomes converted into an irritant.

(2) Expeditiousness. The mould may be made in about half the time required by the ordinary methods, for there is no time wasted by taking the mould of the matrix and trimming with scissors, etc., as one cut round with a penknife directly the foil is folded will suffice.

Then again there is no water required to damp the moulds as they will not adhere to the suppository, but can be easily detached when cold.

I do not claim that this method is by any means perfection, but I myself have proved it much superior to any other I have heard of, and perhaps if anyone who has a few suppositories to make were to try it they would be pleased with it. It is not offered without having been tested, as I have made as many as perhaps fifty dozen by the method.

AN APPRENTICE.

Sacerdos.—You will find formulæ for tincture and wine of boldo on p. 406 of the present volume.

Erratum.—On p. 984, col. i., line 10 from bottom, *for* "Tinct. Sulph.," *read* "Zinci Sulph."

"*Deus.*"—We know of no law regulating the practice of drawing teeth either "on or off the premises."

"*A Student.*"—You may find the information in any elementary work on chemistry.

G. Watt.—(1) *Lotus vulgaris.* (2) *Lepigonum rubrum.* (3) *Geum urbanum.* (4) *Vicia sepium.* (5) *Silene inflatum.* (6) *Alliaria officinalis.* (7) *Potentilla tormentilla.* (8) *Lathyrus macrorrhizus.*

G. C. Druce.—(A) *Arrhenatherum avenaceum.* (A 2) Yes; *Aira flexuosa. C. divulsa.* Yes; *L. multiflora congesta.* (4) *Poa trivialis. Polygala depressa.* The *Crepis* is probably *C. taraxacifolia*, but send a specimen in fruit.

"*Inquirer.*"—The sections of the Pharmacy Act, 1868, relating to the Register of Chemists and Druggists apply to persons keeping "open shop for the retailing, dispensing, or compounding of poisons," and do not extend to or interfere with the business of wholesale dealers in supplying poisons in the ordinary course of wholesale dealing.

"*Botanist.*"—Bentall's botanical paper may be obtained from Mr. Van Voorst, Paternoster Row.

W. H.—There is much virtue in an "if." We do not believe that a public company can legally carry on the business of a chemist and druggist.

"*Preston.*"—Several articles have appeared in this Journal respecting the antiseptic properties of carbolic acid, salicylic acid, borax, and other substances.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Billings, Clapp and Co., Mr. Stokoe, Mr. Hime, Mr. Bell, Mr. Pollard.

INDIAN BARKS CONTRIBUTED TO THE MUSEUM.

BY JOHN ELIOT HOWARD, F.R.S., ETC.

Whilst recently engaged, at the request of the authorities of the Pharmaceutical Society, in revising the list of the barks of the genus Cinchona in the Museum at Bloomsbury Square, I noticed the absence of good and sufficient specimens of the barks now produced from the plantations in India.

This is especially to be regretted, since the collection does not represent the success which has so happily attended the great experiment of the cultivation of these plants, in the varied climates and greatly diversified circumstances into the midst of which they have been transplanted. As the importation of these barks from India is now becoming an important feature in commerce; and as they furnish an increasingly important material for the extraction of quinine and other alkaloids; I shall have pleasure in endeavouring to supply, to some extent at least, the above deficiency.

At present I confine myself to the bark of *C. officinalis*, as quite recently sent home from the Government plantations at Ootacamund (Madras Presidency). From these I have selected four specimens of varying aspect, the examination of which chemically has been carried out by my nephew, David Howard, F.C.S., to whose paper * I may also refer for highly important information, illustrated by additional specimens.

The barks were sent mingled together in one common importation. I will therefore distinguish them by the letters of the alphabet, since I view them all as varied forms of *C. officinalis*. I may premise, however, that (A) presents specially the characteristics of the sort called *crispa* at Ootacamund, but which appears to be wholly unlike the *crispa* of Tafalla, which I have figured in my 'Nueva Quinologia,' and which (as there observed) may be specially distinguished by its *hirsute* scrobicules. This kind —the *Quina fina de Loja*—is growing, I believe, in Ceylon, but not on the Indian continent. In 1869 I sent a typical specimen of it to Mr. Broughton, who replied—"The leaf you sent of *crispa* is markedly different from ours. Our *crispa* has a leathery leaf and strongly marked scrobicules; but it verges into other varieties, that only the more typical plants can be positively identified." I may add, that I sowed the seed from the capsules of a well marked botanical specimen (No. 6 at Kew, and with me) sent from Ootacamund, and obtained two trees—one of the variety *angustifolia* (No. 11),† which is very rich in quinine; the other still living, and a tall plant, of which the foliage sometimes verges towards the *angustifolia*, and sometimes is scarcely distinguishable from the normal *C. officinalis*. I quite agree with Mr. McIvor in his remarks‡ on the narrow leaved variety that it is "*only* a variety, and consequently will not come twice from seeds;" and with Mr. Broughton, who says,§ "The trees No. 11 are now in bud—one has already flowered and seeded, and when in flower did not appear to differ from the other *C. officinalis* blossoms;" and again,‖ "Some further experience quite supports your view that it (the *angustifolia*) is a crown bark. I can now trace all gradations into the Bonplandiana type."

It seems to me that the *crispa* of Ootacamund is only a form of the *C. officinalis*, and the *angustifolia* a scarcely to be distinguished form of the *crispa;* and as the *crispa* of Tafalla is quite another thing, I would suggest the discontinuance of the term *crispa* as being previously appropriated by Tafalla to another kind.

The results of the chemical examination were as follows:—

(A)	Quinine	4·70
	Cinchonidine	0·90
	Quinidine	0·30
	Cinchonine	0·50
	Total	6·40
(B)	Quinine	4·10
	Cinchonidine	1·30
	Quinidine	0·10
	Cinchonine	0·20
	Total	5·70
(C)	Quinine	3·20
	Cinchonidine	1·00
	Quinidine	trace
	Cinchonine	0·10
	Total	4·30

(D) Root bark of *C. officinalis*, which contains about 6 per cent. of mixed alkaloids, largely quinine.

In my examination of Pavon's collection of Peruvian barks in the British Museum, published in the *Pharmaceutical Journal* in 1853, I expressed my belief, that "the old original *crown bark*, the fine loxa of Uritusinga was one which well merited its character on account of the quantity of alkaloids contained." We now find this supposition verified; and the old *crown* bark reappearing in all its original richness in the Government plantations in India. The old characteristics of the bark, as to external appearance, attract notice; as is manifest by comparison with the descriptions of the "*knotty loxa*" of Jussieu, and the *quina de loxa* gathered by Humboldt and described by Haynes; also to very old specimens existing in the museums of the College of Physicians and various hospitals in London, and in my own collection, as gathered by Pavon and others.*

I refer to my "Examination" quoted above for descriptions of the remarkable care and precautions taken (or supposed to be taken) in the gathering of these distinguished barks from the mountains of Uritusinga, Cajamuna, and Guatisinga, under the superintendence of a distinguished botanist—the best being selected for the royal pharmacy. This was in the palmy days of the Spanish monarchy,—days which do not seem likely to return; and now "the crown" is content to partake with "the million" in the worthless barks furnished by Peru,—cheapness rather than efficiency being the recommendation.

* This paper will be published in the next number of this Journal.

† A botanical specimen of this valuable kind is now in the Herbarium of the Pharmaceutical Society.

‡ *In lit. penes me*, June 29, 1869.

§ *In lit.*, April 24, 1869.

‖ *In lit.*, July 6, 1869.

* I am indebted to Dr. Weddell for a specimen of "Cascarilla Colorada from the mountain of Cajamuna, near Loja, *brought from Peru by Jos. Jussieu*, who considered it as the most efficacious bark, and almost lost in his time."

The reader who wishes further information on the value of these may refer to the descriptions of *C. villosa*, *macrocalyx*, *lutea*, *ovata*, etc., in my 'Quinologia;' and, having studied these barks experimentally and medically, he may perhaps be disposed to think that the barks of the different varieties of common willow would be preferable, and more for the patient's benefit.

It is probable that the barks grown in the East Indies will shortly supersede the above-named sorts in pharmacy. In this case it should be understood that the alkaloids are different in the barks of *C. officinalis* and of *C. succirubra*. In the recent examinations Cinchonidine is noted separately from Quinidine, which was not the case in 1853. Also it will be seen that in the *rich* Loxa barks, such as those now sent, Quinine is the chief ingredient. This is not always the case, especially in the poorer sorts, where the place of this alkaloid is often taken by Cinchonidine, as I have before noted in the *Chahuarguera*. It is a mistake to suppose that Cinchonine* is abundant in the *true* Loxa barks, though it may be in those of Jaen (*C. macrocalyx*, etc.).

The alkaloids contained in *C. succirubra* are numerous, and vary under different circumstances of growth to a great extent, Cinchonidine generally being markedly prevalent. But the chief circumstance, respecting which it may be well to sound a note of warning, is the extraordinary difference in the state in which the astringent or tannin material exists in the bark. I have made a great number of experiments on different barks in this respect, and with varied reagents. The result has been a firm conviction that a widely differing medical effect must result from such diverse ingredients in a decoction or infusion of tincture of bark. The *officinalis* and *succirubra* are two of the most remarkably contrasted barks in the above respect; and it might be worth the inquiry of our medical men whether there is any ground for the prejudice which seems to have been entertained in South America against the *red* barks, as being of a heating nature. For myself I have no opinion to offer; but, if I were compelled to resort to either of these barks as a tonic, I should like to know which was the most likely to produce a good effect; and in this respect I suppose that I am not peculiar. But where shall the information be obtained?

* Cinchonine and Cinchonidine were often confused in the early analyses of bark.

THE RESTORATION OF WRITING EFFACED BY SEA WATER.

BY THOS. GARSIDE.

A letter which had been submerged in the wreck of the unfortunate "Schiller," and in which the writing was quite illegible, was shown to me, with the request that I would suggest a means of restoring it. As the method adopted proved completely successful I describe it for the benefit of those who may be called upon under similar circumstances. The letter was carefully brushed over with solution of sulphocyanide of potassium (1 in 20) and then, still damp, held over a dish containing hot hydrochloric acid. The writing was thus developed of a deep red colour. The rationale of the process is this: The iron of the ink is precipitated as peroxide upon the fibres of the paper, and remains when all other colouring matters are washed away. Being in an insoluble form however, no effect is produced by the reagent until the fumes of the acid have rendered it soluble. Probably ferrocyanide of potassium would answer as well or better than sulphocyanide.

Southport, June 1, 1875.

DETECTION OF METHYLIC ALCOHOL IN ETHYLIC ALCOHOL.*

BY A. RICHE AND C. BARDY.

The authors find that the method described by Dumas and Peligot for detecting the presence of wood spirit by converting it into oxalate of methyl, is not applicable when the wood spirit is accompanied by any considerable proportion of ethylic alcohol. Although the crystals of oxalate are easily obtained when operating upon even traces of methylic alcohol alone, yet in the presence of ethylic alcohol the crystals of oxalate of methyl are dissolved in the oxalate of ethyl, or the two ethers unite to form mixed compounds that affect the liquid state. They consider, however, that they have arrived at a solution of the problem by means of the coloured products, differing in shade and stability, which are yielded by the careful oxidation of ethyl-aniline and methyl-aniline. The following is the method, which must be rigorously followed:—

Ten cubic centimetres of the alcohol are introduced into a small flask, together with 15 grams of iodine and 2 grams of red phosphorus, and immediately distilled, the product being collected in about 30 or 40 c.c. of water. The alcoholic iodide which sinks to the bottom of the liquor is separated by means of a pipette and collected in a flask containing 6 c.c. of aniline. The mixture becomes heated, the reaction being aided by keeping the vessel during some minutes in warm water, or moderated, if necessary, by means of cold water if it should enter into a vigorous ebullition. At the end of an hour very hot water is poured into the flask to dissolve the crystals formed, and the liquor is heated to boiling for two or three minutes until it is quite clear. An alkaline solution is then added, which sets free the bases under the form of an oil, which is brought level with the neck of the flask by the addition of sufficient water.

The oxidation of the base may be accomplished by bichloride of tin, iodine, chlorate of potash, or, better still, by a mixture indicated by Hofmann, which is formed of 100 grams of quartz sand, 2 grams of chloride of sodium, and 3 grams of nitrate of copper. One cubic centimetre of the oily liquid is poured upon 10 grams of this mixture and carefully incorporated with it by means of a glass rod; it is then introduced into a glass tube 2 centimetres in diameter, and kept at a temperature of 90° C. in a water-bath during eight or ten hours. The mixture is then exhausted in the same tube by three treatments with warm alcohol, which is thrown upon a filter and made up to 100 c.c.

Pure alcohol gives a liquor of a reddish tint. Alcohol containing 1 per cent. of methylic alcohol gives a liquor manifestly violet by the side of the preceding. With 2·5 per cent. of methylic alcohol the shade is a very distinct violet, and with 5 per cent. it is considerably darker. By comparison in tubes of the same calibre with mixtures containing known quantities of the alcohols, a fair idea may be obtained of the amount of wood spirit in any given specimens.

The ordinary colorimetric methods give good results, but greater precision may be attained by adding 5 c.c. of the liquid to 95 c.c. of water, and pouring 5 c.c. of this new solution into 400 c.c. of water contained in a porce-

* Abstract of a paper read before the Academy of Sciences (*Comptes Rendus*, vol. xxx., p. 1076).

lain capsule and heating it in a boiling water-bath. Small fragments of white merino, free from sulphur, are then placed in the solution and kept there half an hour, after which time they are removed, washed and dried. If there has been no methylic alcohol present the stuff remains white; but 1 per cent. gives a violet tint which perceptibly increases in depth with the proportion of methylic alcohol.

TOUGHENED GLASS.*

A very interesting paper on Toughened Glass has recently been read before the Society of Arts, by Mr. Perry F. Nursey, C.E., in which he describes the process of M. de la Bastie for tempering glass and giving it an extraordinary degree of tenacity. The paper is printed in the *Journal of the Society of Arts* for June 4, and the following is taken from it.

After briefly sketching the history of the glass manufacture, Mr. Nursey referred to the curious physical phenomena exhibited by unannealed glass as exemplified in the Bologna phials and Prince Rupert's drops, and described the ordinary methods of annealing. During the thirty centuries over which the history of the glass manufacture extends it does not appear that any process has been invented by which the inherent brittleness of glass and its liability to fracture have been successfully overcome and at the same time its transparency preserved. It has remained for our own times, which have seen such remarkable scientific developments, to witness the production of a process by which glass is practically deprived of its brittleness. The inventor of this process is M. Francois Alfred de la Bastie, a French gentleman of property, who was educated as an engineer.

Many years since M. de la Bastie was impressed with the desirability of rendering glass less brittle, and so extending the sphere of its usefulness. Aware that the fragility of glass results from the weakness of the cohesion of its molecules, he thought that, by mechanically forcing the molecules closer together, and rendering the mass more compact, the strength and solidity of the material would be increased. This is exactly the line of argument an engineer would follow—it is one which led Sir Joseph Whitworth to produce the well-known Whitworth metal. M. de la Bastie found, however, after long trial and experiment, that mechanical compression failed to influence glass in the slightest degree, even when applied while the material was in a fluid or soft condition. He therefore changed his tactics, and commenced to apply to glass a system of tempering, such as is usually applied to steel, namely, submitting it to a bath of heated oil. He knew that by immersing heated glass in cold water he would only put the material in a state of unstable equilibrium, so that the least shock would cause it to break up, as in the case of the Rupert drops. He then sought to invert this result, to diminish, or even to remove, the extreme fragility of glass by tempering it by immersion in a fluid other than water. In attaining this object two essential objects had to be determined. Firstly, the point at which glass can be tempered without being put out of shape, and secondly, the medium to be employed for the immersion of the glass. The first condition M. de la Bastie found to be that degree of heating at which softness or malleability commences, when the molecules are capable of closing suddenly together, condensing the material when it is plunged in a liquid at a somewhat lower temperature. The second condition he found was satisfied by having a fluid capable of being raised to a much higher temperature than that of boiling water, without entering into a state of ebullition. For this purpose, and after a long series of experiments, M. de la Bastie devised an oleaginous compound, formed of oils, wax, tallow, resin, and other similar ingredients in certain proportions.

Although the invention is apparently a most simple one, there are many delicate conditions involved, the disregard of any one of which constitutes the precise difference between success and failure. It thus happened that, seven years since, just as M. de la Bastie had perfected his invention, and had produced highly satisfactory results, he lost the clue to his success, and for two years was baffled in every attempt to re-discover it. He at length succeeded in regaining his secret, and has since been engaged in perfecting his invention, and putting it into a practical shape. He had to carefully adjust all the numerous details, for although the invention consists in simply heating the glass, and dipping it while hot into a heated oleaginous bath, there are many conditions involved. Thus glass articles may be underheated and will not be susceptible to the effect of the bath, or they may be overheated, and will lose their shape; or, again, they may be heated to the right temperature, and yet be spoiled during the process of transference into the bath. Then, again, the exact proportions of the oleaginous constituents of the bath, and their precise temperature, have an important influence upon the ultimate result. All these points, however, with many others, have been definitely settled by M. de la Bastie, who has for some time past worked his process experimentally, and is now erecting a factory in France, in which to carry it on practically and commercially.

In carrying out his process, M. de la Bastie finds it necessary to raise the glass to be tempered to a very high temperature. The hotter it is the less the risk of breaking the glass, and the greater the shrinkage or condensation. Hence the advantage, and often the necessity, of heating the glass to the point of softening, which is attended by the difficulty that glass in the soft condition gets readily out of shape, so that it must be plunged into the bath almost without touching it. In plunging the hot glass, too, into a heated combustible liquid the latter is apt to take fire. These difficulties M. de la Bastie has overcome by placing the tempering bath in immediate communication with the heating oven, and covering it so as to prevent access of air. The oven being charged with the articles to be tempered, they are made to slide into the adjoining bath without being handled, and the contents of the bath, having no supply of external air, are not liable to inflame. In order that the shape of the tempered articles may not be affected, particularly flat glass, the floor of the oven is made to cant, so that when the glass is heated on it, it is turned to a sloping position, and the glass slides into the bath, along a surface arranged in it at the same angle as that of the oven floor. To avoid the clearness of the glass being affected by the dust of the furnace flame, which is apt to settle on the glass and chill its surface, the glass is heated in a muffle, to which the flame has no access, being applied externally. The shock of the fall of glass into the bath is prevented by fixing in it a sheet of wire gauze, or asbestos fabric, for the glass to fall on.

Of course the condition of working would be considerably modified if glass manufacturers adopted the toughening process in their own works. In such case the toughening process would simply take the place of the present annealing process, than which it is said to be much more speedy and economical. The glass would then be treated just at the point at which it passes from the fluid to the solid condition, and would not require reheating. By the substitution of this process for that of ordinary annealing, the saving, it is claimed, would be considerable. There would be the saving of the fuel used in the annealing ovens; the saving of the time required for annealing; the saving in breakages, besides a saving in labour.

The physical change which glass thus treated undergoes is complete and remarkable. Its extreme brittleness is exchanged for a degree of toughness and elasticity which

* Abstract of a paper in the *Journal of the Society of Arts*, June 4, 1875.

enables delicate glass articles to be thrown about indiscriminately, and more substantial ones to resist the impact of heavy iron weights falling from considerable heights. Mr. Nursey states that upon his first making the acquaintance of toughened glass articles at the offices of the representatives of M. de la Bastie—watch glasses, plates, dishes, and sheets of glass, both coloured and plain, were thrown across a large room, and fell spinning on the floor. Water was boiled in a tempered glass saucer for some time over a brisk fire, and the saucer was quickly removed to a comparatively cold place, and stood on iron, but was in no way affected by change of temperature. A small piece of plate glass was held in a gas flame until the corner became very hot. The glass proved a bad conductor of the heat, which did not extend any appreciable distance beyond the point of contact with the flame, neither was the glass cracked from unequal expansion, nor was it damaged by sudden immersion in cold water. In order to judge of the comparative resistance offered by untoughened and toughened glass to the force of impact, a piece of the former, measuring six inches by five inches by one-eighth inch thick, was supported in a frame about half an inch from the floor. A two-ounce brass weight was then dropped upon it from twelve and eighteen inches respectively without damage, but on the height being increased to twenty-four inches the glass was broken into several fragments. A piece of toughened glass of the same size but rather thinner, was then treated in the same way, at heights increasing a foot at a time, up to ten feet, but without producing the slightest visible impression. It is possible, however, that, by the repetition of the blows, the structure of the glass may have become imperceptibly altered, as it is known that by repeated blows the fibrous nature of wrought iron becomes exchanged for the crystalline character of cast iron. Finding the two-ounce weight to make no impression, an eight-ounce iron weight was substituted, and was dropped on the glass from a height of two feet, and then of four feet, without fracturing it. On the height being increased to six feet, however, the glass broke with a distinct report. But here another phenomenon presented itself; instead of the toughened glass being broken into some twelve or fifteen large angular pieces, as was the ordinary glass, it was literally reduced to atoms. There were, it is true, some pieces about half an inch square, but these were traversed in all directions by delicate lines of fracture, and, on being gently touched, crumbled into small pieces, and many of these small pieces were easily reduced by gentle pressure into mere atoms, so thorough and so complete does the disorganization of the entire mass appear to be. A similar result is produced by placing a piece of toughened glass flat on the table with a corner projecting over, and endeavouring to chip the corner off with a hammer. The corner will, after a series of smart blows, be broken off, but the whole mass will be at the same moment disintegrated and reduced to atoms. Another peculiarity about toughened glass is that the fragments are by no means so sharp, and therefore not so capable of piercing the flesh, or of causing incised wounds, as are those of ordinary glass.

One important point of difference between M. de la Bastie's toughened glass and Prince Rupert's drops is that, although the skin of the former may be scored through with the diamond, the body cannot even then be broken through by ordinary force, much less does the mass fly to pieces and disintegrate, as in the case of the Rupert drops. Toughened glass is also readily susceptible of a high degree of polish, and it can be cut by the wheel for lustre work and such like. The glass can likewise be engraved, either by hydrofluoric acid, or by Mr. Tilghman's sand-blast process. It will thus be seen that toughened glass presents features which appear to some extent paradoxical.

It would appear that toughened glass possesses enormous cohesive power, but that if the equilibrium of the mass is disturbed at any one point, the disturbance, or disintegration, is instantaneously communicated throughout the whole piece, the atoms no longer retaining the power of cohesion. It is as though the glass was endued with a nervous system, a shock to which at any one point instantly and utterly demoralized the whole. It is important to note that neither transparency nor colour in glass is in any way affected by the process of toughening, and the ring, or sound emitted upon the glass being struck, is nearly as clear in toughened as in plain glass.

In order to determine the relative values of ordinary glass and the toughened material, as regards their strength, the following experiments, with the view of ascertaining their respective resistances to ordinarily applied stress, have been carried out by the aid of Mr. Kirkaldy's testing machinery.

Twenty pieces of glass were submitted to bending stress, ten being toughened and ten untoughened. The glass was of French manufacture, and was that known as "Rive de Giers." Each piece of glass measured, as nearly as possible, six inches in length by five inches in breadth, and the samples had a mean thickness of ·2259 of an inch. Each piece was placed with a bearing of half an inch at each end, and the weight was brought gradually upon the centre, in some instances by the testing machine and in others by direct weights. Taking two pieces of glass, having about the same sectional area—the one tempered and the other untempered—Mr. Kirkaldy's certificate shows that the untempered glass yielded under a strain of 279 lbs., whilst the toughened glass did not give way until a stress of 1,348 lbs. had been reached. The same proportion, however, did not occur throughout the series, the toughened glass giving in some instances lower results. This arose from two causes, the diminished area of some of the samples of glass, and from the fact that, in some instances, the process of toughening had not been perfectly carried out; for the samples were prepared by M. de la Bastie under purely experimental conditions. The imperfect tempering was made manifest, after the destruction of the glass, in three ways chiefly, firstly, by the glass showing needle fractures, such as are seen in untoughened glass; secondly, by a faint milky line presenting itself in looking at the glass in section; and, thirdly, by portions of the glass, a square inch in area, remaining unfractured, whilst the whole surrounding mass was reduced to atoms. But above and beyond all this, it was evident that the strains applied were such as could not possibly come upon glass articles in ordinary use; they were long-sustained pressures, tending at every increment of weight to alter the relative position of the particles of the glass, but affording them no opportunity of returning to their normal position, or, in other words, of utilizing the elasticity of the mass. Glass articles in ordinary use are subject to sudden sharp blows, either from falling down, or from some extraneous substance being brought smartly in contact with them. Under these conditions the elasticity of toughened glass is called into play and enables it to sustain a shock immeasurably beyond that which would suffice to destroy ordinary glass, as is shown by the experiments first described. Hence the proper tests for glass, either toughened or plain, are precisely those of smart and sudden impact, and not of prolonged stress.

Examination and experiment with this remarkable substance have revealed a number of most interesting facts with regard to its physical character. The microscope reveals the fact that the fractures follow a regular order, which gives a uniform shape to the crystals which they produce. Large crystals can be subdivided into several smaller ones with a similar result. The edges of the atoms, too, are not jagged and serrated, as are those of ordinary glass, hence their diminished tendency to cause incised wounds, as already mentioned. This peculiarity would afford a means of ascertaining whether the glass had been tempered or not.

The physical character of toughened glass has been made the subject of careful investigation by M. Victor de Luynes. As a general result, M. de Luynes has found that toughened glass will bear from 80 to 100 times the strain of ordinary glass. M. de Luynes also examined both plain and toughened glass by the aid of polarized light, the results of his examination going to show that toughened glass owed its peculiar characteristics to a condition of intensified compression.

LEECHES IN ANJOU.*

BY C. MÉNIERE, OF ANGIERS.

It is well known to the leech fishers of Anjou that certain waters cannot support leeches, and that the conformation of the banks may be prejudicial to their reproduction, whilst others, on the contrary, yield continually a relatively abundant collection. If some industries progress there are others that remain stationary; for although in Anjou on rare occasions a leech fisher may be seen who uses a net with fine meshes, fixed at the end of a pole intended to stir up the marshy waters, there are others who content themselves with placing their legs in the midst of the swamp and allowing the leeches to fasten on to them.

The fishers usually like calm weather, with not too high a temperature; some prefer to work in stormy weather, before sunrise, or in the evening at sunset. Moreover, upon searching, with the aid of a lamp, the borders of a marsh where the vegetation is developed, a good number of leeches may be found attached to the branches and leaves of certain plants.

Anjou possesses nearly all the species of leeches as well as numerous varieties. There exists a considerable difference in certain species, according to the marsh in which they are found. For instance, the experienced fisher can distinguish the official leech which has lived in a marsh in the midst of vegetation, for in other conditions it no longer presents the same character. It is also believed by some persons that the colour of the water influences the colour of the leech, and the greater or less development of the characters by means of which they are classified. Although the author attributes only a secondary importance to this point, he considers that the chemical nature of the water affects the abundance or scarcity of the leeches. Thus they are not found in the calcareous and ferruginous waters, whilst the waters reposing upon schist beds, which are slimy at the bottom and charged with aluminous *débris*, yield seven or eight species.

The author describes some leeches as parasites and some as sedentary. He uses the term "parasite" because, for instance, the leech of the species *Pisciola piscium*, as soon as it possesses sufficient agility, attaches itself to the tench, roach, or the back of the young pike, making its way to the neighbourhood of the gills, sucking the blood and growing; neither is it detached until it is well gorged and developed. Hence this species is found not only in ditches and marshes, but also in open water in rivers, among stones, and especially slates.

The *Hirudo geometra* is not rare in Anjou. It never remains in the marshes—at any rate while young—preferring the schistous sides of streams, and clinging to the young fish which seek the borders of limpid streams. These two species, which appear to have the same habits, become in their turn a prey to the pike.

The other species, which he calls sedentary, scarcely quit their native marshes. The *Hirudo vulgaris* is sometimes carried by the current into a river, but it prefers the running water of ditches, or brooklets covered at the bottom with vegetable *débris*, such as twigs and branches, which serve it as a resting place. The *Hæmopis sanguisuga*, commonly called the horse leech from its fastening on the flesh of horses turned into the marshes or humid pastures, is always found where the water is shallow, and by preference in that which is miry. It lives very well in water charged with organic matters, and attacks salamanders, frogs, the fry of fish, etc.

* From the *Répertoire de Pharmacie*, iii., 306.

ZEBRA WOOD.*

BY JOHN R. JACKSON.

In a paper "On the Identity of Goa Powder and Araroba," read before the Pharmaceutical Society on April 7 last, and published in the Society's Journal for April 10 (p. 801), Mr. E. M. Holmes, the author, refers incidentally to the botanical source of zebra wood, and, quoting from Martius's 'Flora Brasiliensis,' refers it to *Centrolobium robustum* Bth., a large leguminous tree bearing winged fruits very similar in shape to those of the maple, but very much larger. In the discussion which ensued upon Mr. Holmes's paper Professor Bentley took occasion to show that, according to Schomburgk, zebra wood is derived from *Omphalobium Lamberti*, a tree of Guiana, belonging to the Connaraceæ. This reference to a valuable ornamental wood opens a question of some interest, inasmuch as a good deal of doubt has hitherto existed regarding the source of zebra wood.

In Holtzapffel's 'Descriptive Catalogue of the Woods Commonly Employed in this Country for the Mechanical and Ornamental Arts,' the botanical notes to which are by Dr. Royle, zebra wood is described as the produce of the Brazils and Rio Janeiro. Its colour is described as orange-brown and dark brown variously mixed, generally in straight stripes. It is considered by cabinetmakers to be intermediate in general appearance between mahogany and rosewood, so as to form a pleasing contrast with either of them. It is used in cabinetwork and in turnery, and has a very handsome appearance when polished. It is described as being "sent in logs and planks as large as 24 inches." No reference is made to the tree furnishing it, but from a note we are told that "zebra wood is also called pigeon-wood by Browne. One kind of pigeon-wood in Jamaica is Guettarda speciosa; another kind, called also zebra wood, is described by Browne, but he was unable to make out the genus." What this last may have been we are unable to say; it seems clear, however, that none of the zebra wood of commerce comes from the West Indies, though Grisebach, in his 'West Indian Flora,' tells us that the name is applied to *Eugenia fragrans*, var. *cuneata*. So far as we have been able to make out, Martius's description and identification of the zebra-wood of Rio de Janeiro with *Centrolobium robustum* seems correct, and Schomburgk's identity of *Omphalobium Lamberti* with that of Guiana is probably also correct, for we are told by one of the largest importers of foreign woods in this country that the best zebra wood comes from Rio de Janeiro, the next best from Bahia, which may, perhaps, also be the produce of *Centrolobium*. Honduras supplies an inferior sort, although the wood is larger in diameter. Of the tree furnishing this kind we have no information; that obtained from Demerara, which undoubtedly is furnished by *Omphalobium Lamberti*, is of a poorer class than all the preceding, a wood of a similar quality commercially being produced in Nicaragua, to the botanical origin of which we have no clue.

From these remarks it will be seen that zebra wood is the produce not of one tree but of several, two of which it may be considered are pretty satisfactorily settled, namely, that the Rio de Janeiro zebra wood is obtained from *Centrolobium robustum*, and the Demerara sort from *Omphalobium Lamberti*. There is a peculiar mystery hanging over the origin of most of the South American woods, many of which are highly ornamental, and are imported in large quantities, considering the uses to which they are put. Thus, for instance, a wood known in the trade as angica wood, which is very similar in appearance to zebra wood, was at one time shipped in quantity from Parahiba and Paranahiba (Brazils), but its origin was never known, and its importation has ceased for many years.

Museum, Kew.

THE PHYSIOLOGICAL ACTION OF LIGHT.*

BY JAMES DEWAR, F.R.S.E.

The late Sir Henry Holland, President of the Royal Institution, in his essay on the "Progress and Spirit of Physical Science" (1858) says, "The experiments of D'Arcy prove that the impression of light is often retained on the retina for fully two and a half minutes, the time in which a luminous particle or undulation passes through nearly thirty millions of miles of space! What is the condition of light—be it conceived as matter, or motion, or force—when thus arrested and enchained in a living organism?"

To this profound problem of the specific effect produced on the retina and optic nerve by the action of light, Mr. Dewar and Dr. John G. McKendrick have especially directed their attention. Numerous hypotheses have been made from time to time by physicists and physiologists; but up to the present date our knowledge of the subject is without any experimental foundation. For example, Newton, Melloni, and Seebeck stated that the action of light on the retina consisted of a communication of mere vibrations; Young conjectured that it was a minute intermittent motion of some portion of the optic nerve; Du Bois-Reymond attributed it to an electrical effect; Draper supposed that it depended on a heating effect on a choroid; and Mosier compared it to the action of light on a sensitive photographic plate.

It is evident that, in accordance with the principle of the transference of energy now universally accepted, the action of light on the retina must produce an equivalent result, which may be expressed, for example, as heat, chemical action, or electro-motive power. It is well known that the electro-motive force of a piece of muscle is diminished when it is caused to contract by its normal stimulus, the nervous energy conveyed along the nerve supplying it; and similarly a nerve suffers a diminution of its normal electro-motive force during action. In the same manner, the amount and variations of the electro-motive power of the optic nerve affected secondarily by the action of light on the retina, are physical expressions of certain changes produced in the latter; or, in other words, are functions of the external exciting energy, which in this case is light. Considerations such as these led them to form the opinion that the problem of what effect, if any, the action of light has on the electro-motive force of the retina and optic nerve, would require for its investigation very careful and refined experiment.

The inquiry divided itself into two parts—first, to ascertain the electro-motive force of the retina and nerve; and, second, to observe whether this was altered in amount by the action of light. The electro-motive force of any living tissue can be readily determined by the method of Du Bois-Reymond. This great physiologist found that every point of the external surface of the eyeball of a large tench was positive to the artificial transverse section of the optic nerve, but negative to the longitudinal section. This he accomplished by the use of his well-known non-polarizable electrodes, formed of troughs of zinc carefully amalgamated, containing a solution of neutral sulphate of zinc, and having cushions of Swedish filter paper on which to rest the preparation. (To protect the preparation from the irritant action of the sulphate of zinc, a thin film, or guard of sculptor's clay, moistened with a ·75 per cent. solution of common salt, and worked out to a point, was placed on each cushion.) These electrodes were connected with a galvanometer, and the preparation was placed so that the eyeball, carefully freed from muscle, rested on the one clay guard, while the transverse section of the optic nerve was in contact with the other. By following Du Bois-Reymond's method the experimenters had no difficulty in obtaining a strong deflection from the eyes of various rabbits, a cat, a dog, a pigeon, a tortoise, numerous frogs, and a goldfish. The deflection was frequently so much as to drive the spot of light off the galvanometer scale.

With regard to the second question—namely, Whether, and to what extent, the electro-motive force would be affected by light? more difficulty was found. The method followed was to place the eyeball on the cushions in the manner above described, to note the deflection of the galvanometer needle, and then to observe whether or not any effect was produced on the impact of a beam of light during its continuance and on its removal. In a few of the earlier experiments Du Bois-Reymond's multiplying galvanometer was used, but finding the amount of deflection obtained was so small that the effect of light could not be readily observed, they latterly used Sir William Thomson's exceedingly sensitive reflecting galvanometer, kindly lent them by Professor Tait. They met also with secondary difficulties, such as the dying of the nerve, the impossibility of maintaining an absolutely constant zero, and an absolutely constant amount of polarity, the effects of heat, etc.; but these difficulties were overcome as far as possible by the most approved methods. The changes in polarity of the apparatus occurred slowly, and could not be mistaken for the changes produced by the action of light, which occurred suddenly, and lasted a short period of time. It is also important to state that the deflections observed do not at present profess to be absolute, but only relative values. About five hundred observations were made previous to April, 1873, and every precaution was taken to obtain accurate results. The effects of heat were carefully avoided by covering over the troughs on which the eye under examination rested, with a spherical double-shell of glass, having at least an inch of water between the walls.

The results arrived at are as follows:

1. The action of light on the retina is to alter the amount of the electro-motive force to the extent of from 3 to 7 per cent. of the total amount of the natural current.

2. A flash of light, lasting the fraction of a second, produces a marked effect.

3. A lighted match, held at a distance of four or five feet, is sufficient to produce an effect.

4. The light of a small gas flame enclosed in a lantern, and caused to pass through a globular glass jar (12 inches in diameter), filled with a solution of ammoniacal sulphate of copper, or bichromate of potash, has also produced a change in the amount of the electro-motive power.

5. The action of light on the eye of the frog is as follows: When a diffused light is allowed to impinge on the eye of the frog, after it has arrived at a tolerably stable condition, the natural electro-motive power is in the first place increased, then diminished; during the continuance of light it is still slowly diminished to a point where it remains constant; and on the removal of light there is a sudden increase of the electro-motive power nearly up to its original position. The alterations above referred to are variable, depending on the quality and intensity of the light employed, the position of the eyeball on the cushions, and modifications in the vitality of the tissues.

6. Similar experiments made with the eye of warm-blooded animals, placed on the cushions as rapidly as possible after the death of the animal, and under the same conditions, have never given an initial positive variation, as detailed in the case of the frog, but always a negative variation. The after inductive effect on the withdrawal of light occurs in the same way.

7. Many experiments were made as to effect of light from different portions of the spectrum. This was accomplished by causing different portions of the spectrum of the oxyhydrogen lime-light to impinge on the eye. All these observations tend to show that the greatest effect is produced by those parts of the spectrum that appear to consciousness to be the most luminous; namely, the yellow and the green.

* Lecture delivered at the Weekly Evening Meeting of the Royal Institution of Great Britain, Friday, February 5 1875.

8. Similarly, experiments made with light of varying intensity show that the physical effects observed vary in such a manner as to correspond closely with the values that would result if the well-known law of Fechner was approximately true.

9. The method followed in these inquiries is a new method in physiological research, and by the employment of proper appliances it may be greatly extended, not only with regard to vision, but also to the other senses.

After April 21, 1873, Mr. Dewar and Dr. McKendrick, the experimenters, endeavoured to obtain quantitative results, involving time as a variable element in the case of the action of light on the retina and optic nerve. They therefore found it necessary to construct a true graphical representation of the variations of the electro-motive force occasioned by the impact and cessation of light. It is clear that to register minute galvanometrical alterations, the only plan that could be employed would be to photograph on a sensitive surface, covering a cylinder rapidly revolving on a horizontal axis, the alteration of position of the spot of light reflected from the mirror, just as continuous magnetic observations are registered. As the apparatus required to execute these observations is very complicated, and would require much preliminary practice, they in the meantime adopted a simpler method of registration. This plan was to note the position of the galvanometer at equal intervals of time before, during, and after the impact of light on the eye. In these observations they used a seconds pendulum giving a loud beat. One observer read aloud the galvanometer; the other marked every interval of two and a half seconds, registered the numbers obtained, and regulated the supply of light. A little practice in the method above described enabled them to obtain very satisfactory results, agreeing very closely in different observations, and showing in a decided way the salient points of the variation curve.

These curves show that on the impact of light there is a sudden increase of the electro-motive force: during the continuance of light it falls to a minimum value, and on the withdrawal of light there is what they termed an *inductive effect*, that is to say, a sudden increase of the electro-motive force which enables the nerve to acquire its normal energy. The falling off of the electro-motive force by the continued action of light is the physical representative of what, in physiological language, is called fatigue; the inductive effect exhibiting the return of the structure to its normal state. Occasionally the impact of light is not followed by a rise in the electro-motive force, but by a diminution. This is probably to be explained by the fact, that the death of the retina and nerve is indicated by a gradual falling of the electro-motive force, and that this change frequently goes on so rapidly that the impact of light is unable to produce any rise. In these circumstances, the spot of light, which before the impact of light was slowly moving downwards, is on the impact steadied for a moment, and then pursues its downward course more rapidly.

By several distinct sets of observations:

1. It was proved that though there is no difficulty in obtaining a strong current from the skin of the frog, this current is not affected by light. This observation demonstrates that the pigment cells of the skin in the vicinity of the cornea have nothing to do with the results obtained.

2. The current obtained from a mass of the pigment cells of the choroid does not exhibit any sensitiveness to light.

3. The subcutaneous injection into the frog of woorara, santonin, belladonna, and Calabar bean, does not destroy the sensibility of the retina to light.

4. As to the action of the anterior portion of the eye. On carefully dissecting an eye of a frog, so as to remove completely the anterior portion, including cornea, aqueous humour, iris, ciliary muscle, and lens, and on bringing the retina into actual contact with one of the clay pads, we readily obtained a large deflection, which was as sensitive to light as when the whole eye was employed, thus eliminating any possibility of the contraction of the iris under the stimulus of light having to do with the results previously obtained.

5. On using the anterior portion of the eye, so that the cornea and posterior surface of the crystalline lens were the poles, a large deflection, which was, however, insensible to light, was obtained.

6. The sclerotic and nerve without the retina, in the same manner, gave a large natural electro-motive force, also not sensitive.

7. The distribution of the electro-motive force between the different portions of the eye and cross section of the nerve may be stated as follows:—The most positive structure is the cornea, then the sclerotic, then the longitudinal surface of the nerve; the cornea is also positive to the posterior surface of the crystalline lens, and the retina itself seems to be positive to the transverse section of the nerve.

8. As to the effects produced by lights of different intensities. If a candle is placed at a distance of one foot from the eye, and then is removed ten feet, the amount of light received by the eye is exactly one hundredth part of what is got at a distance of one foot, whereas the electro-motive force, instead of being altered in the same proportion, is only reduced to one-third. Repeated experiments made with the eye in different positions have conclusively shown that a quantity of light one hundred times in excess of another quantity only modifies the electro-motive force to the extent of increasing it three times as much, certainly not more.

9. It was apparent that these experiments would ultimately bear upon the theory of sense-perception as connected with vision. It is now generally admitted that no image, as such, of an external object is conveyed to the sensorium, but that in reality the brain receives certain impressions of alterations taking place in the receiving organ. The natural query then arises, Are the physical effects we have described and measured really comparable in any way with our sensational differences in light perception, when we eliminate all mental processes of association, etc., and leave only perception of difference of intensity? In other words, are these changes the representative of what is conveyed to the sensorium? It would appear, at first sight, that this problem is altogether beyond experimental inquiry. There is, however, a way of arriving at very accurate measures of the variation of our sensational differences in the case of light, and this has been developed theoretically and experimentally by the justly renowned physiologist Fechner. Stating the law of Fechner* generally, we may say the difference of our sensations is proportional to the logarithm of the quotient of the respective luminous intensities. A recent series of experiments by Dalbœuf† has entirely confirmed the truth of this law. If, therefore, the observed difference in electro-motive power, registered under conditions of varying luminous intensity, agree with this law of Fechner, regulating our sensational impressions, then there can be little doubt these variations are the cause of, and are comparable to, our perception of sensational differences. Now, it is stated above, that with a quantity of light one hundred times in excess of another quantity, the electro-motive force only becomes three times greater. According to Fechner's law, we may say the difference of our sensations, with that variation in the amount of luminous intensity, would be represented by 2, the logarithm of 100. The experimental results being as 3 to 1, the difference is also 2, thus agreeing very closely. It is to be remembered, however, that these results have been obtained by experiment on the eye of the frog, but similar changes have been observed in the eyes of mammals. In the latter, however, the amount of alteration is not so great, in all probability owing to the rapid death of the parts.

10. When one clay point is placed in contact with the cornea or nerve, and the other with the section of the optic lobe, a current is at once obtained which is sensitive

* Fechner, 'Elemente des Psychophysik.' Helmholtz, 'Optique Physiologique.'

† Recent Memoir to Belgian Academy.

to light. In this experiment the eye is left in the orbit, and the nerve is uninjured. Thus, the effect of light on the retina has been traced into the brain.

The continuance of these investigations led to the following results :—

1. The light from a beam of uncondensed moonlight, though of weak intensity, and almost entirely free from heat rays, is still sufficient to alter the electro-motive power of the nerve and retina.

2. They examined the phenomenon in the eyes of the following animals : (1) The common newt — *Triton aquaticus;* (2) The goldfish—*Cyprinus auratus;* (3) The rockling — *Motella vulgaris ;* (4) The stickleback — *Gasterosteus trachurus;* (5) The common edible crab—*Cancer pagurus;* (6) The swimming crab—*Portunus puber;* (7) The spider crab—*Hyas coarctaius ;* (8) The hermit crab — *Pagurus Bernhardus;* and (9) The lobster—*Homarus vulgaris.*

The general results with the eyes of these various animals were similar to those previously described. The eye of the goldfish and rockling, both sluggish fishes, were found to resemble each other, inasmuch as the variations in the electro-motive force were slow, and in this respect they presented a marked contrast to those of the active and alert stickleback, the eye of which was very sensitive to light.

The experiments on the eyes of crustacea are of importance, because they show that the action of light on the compound eye is the same as on the simple eye, namely, that it alters the amount of the electro-motive force of the sensitive surface. The eye of the lobster was found to give a deflection of about 600 galvanometical degrees, the scale being placed at a distance of about 26 inches. Light produced a variation in this deflection of about 60 degrees, that is, about 10 per cent., the largest amount of variation yet observed in any eye. It was also demonstrated that the effect of light, diminished in intensity by distance, was exactly what was observed in the case of the simple eye. For example, at the distance of one foot a variation to the extent of about 100° was observed. At a distance of 10 feet, with $\frac{1}{100}$th part of the amount of light, the effect was not 1° but 20°, or $\frac{1}{5}$th of the total amount observed at 1 foot.

3. The action of light on the electro-motive force of the living eye in cats and birds (pigeon and owl) has been observed. In the earlier experiments great difficulty was found in observing sensitiveness to light in the eyes of mammals and birds, when these were removed with the utmost dispatch from the orbit of the animal immediately after death. This was evidently owing to the fact that the sensibility of the nervous system in these animals disappears quickly after the withdrawal of healthy blood. It therefore became necessary to perform the experiment on the living animal. This was done by first putting the cat or bird under the influence of chloroform, then fixing it by a proper apparatus so that the head was perfectly immovable, and lastly removing the outer wall of the orbit with as little disturbance to the ciliary vessels as possible. The optic nerve was now cut, the transverse section directed upwards, and the clay points of the electrodes were now adjusted, one to the transverse section of the nerve, and the other to the cornea. With these arrangements a strong current extremely sensitive to light was at once formed.

4. The effect was traced into the optic lobes of a living pigeon under chloroform. The following were the results of this observation : *a.* When one pole was applied to the left optic lobe, and the other to the cornea of the right eye, a deflection was obtained which was sensitive to light : *b.* When the pole was removed from the right eye and applied to the cornea of the left, a smaller deflection was obtained, also sensitive to light ; and *c.* When light was allowed to impinge on both eyes, while the one pole was in contact with either eye and the other with the left optic lobe, the result was nearly double that produced by the impact of light on one eye alone, either right or left. These effects may be explained by the decussation of the optic nerves in the optic commissure.

5. The eye of the snake was examined, and in its action resembled that of a frog.

6. The law of the variation in the electro-motive force of the retina and optic nerve therefore holds good in the following groups of the animal kingdom, Mammalia, Aves, Reptilia, Amphibia, Pisces, and Crustacea.

7. Many experiments were made which prove that the pyschophysical law of Fechner, previously alluded to, is not dependent only on perception in the brain, but in part on the structure of the eye itself. The effects which occur on, during, and after the action of light on the retina, also take place after the eye has been removed from all connection with the brain. Thus the law of Fechner is not, as has been hitherto supposed, a function of the brain alone, but is really a function of the terminal organ, the retina.

8. A new method was employed for registering galvanometrical variations, which may be of service in many physical and physiological researches. This consists in placing at the proper distance from the galvanometer, instead of the ordinary graduated scale, the surface of a cylinder covered with paper, and moving on a horizontal axis by clock-work. The spot of light reflected from the galvanometer mirror is rendered more precise by having the shade of the galvanometer lamp blackened over the entire surface, with the exception of a spot about three millimetres in breadth, in the centre of which a line or cross is made of soot. The image of this line or cross is of course reflected by the mirror upon the cylinder. When the cylinder is set in motion by the clock-work the spot of light may be accurately followed by the hand of the observer, after a little practice, with a fine brush moistened with ink. The cylinder employed performed a complete revolution in eighty seconds. This time was divided into four equal parts, each representing twenty seconds, by four lines drawn transversely at equal intervals across the paper on the cylinder. The first space, between lines one and two, represented twenty seconds, in which the eye was in the dark, and in which the electro-motive force is represented by a straight line; the second space, between lines two and three, represented twenty seconds, during which the effect of the impact of light took place, and in which the variation of the electro-motive force is indicated either by a curve to the right or to the left; the third space, between lines three and four, represented twenty seconds of continued action of light, during which the electro-motive force gradually rises; and lastly, the fourth space, between lines four and one (the point of starting), representing twenty seconds; during which the electro-motive forces at first rises on the withdrawal of light, and afterwards sink rapidly.

It has been experimentally proved—(1) that the impact of light on the eyes of members of the following groups of animals, viz., Mammalia, Aves, Reptilia, Amphibia, Pisces, and Crustacea, produces a variation amounting to from 3 to 10 per cent. of the normal electro-motive force existing between the corneal surface and the transverse section of the nerve ; (2) that this electrical alteration may be traced into the brain ; (3) that those rays that we regard as most luminous produce the largest variation ; (4) that the alteration of the electrical effect with varying luminous intensity seems to follow very closely ratios given by the psychophysical law of Fechner; (5) that the electrical alteration is due to the action of light on the retinal structure itself, as it is independent of the anterior portion of the eye, eliminating, therefore, the natural supposition that the contraction of the iris might produce a similar result ; (6) that it is possible, by experiment, to discover the physical expression of what is usually called in physiological language fatigue ; and (7) that the method employed in this research may be applied to the investigation of the special organs of the other senses.

The Pharmaceutical Journal.

SATURDAY, JUNE 19, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed " Pharm. Journ."*

THE PHARMACY ACT (IRELAND) BILL.

WE are still unable to give our readers any account of the reception of this Bill in Parliament, since its second reading has been again postponed to the end of another week. Up to Friday, the 11th inst., the King and Queen's College of Physicians in Ireland continued alone in the support of this projected measure, while the total number of petitions presented against it up to the same date were 170, bearing 2,167 signatures. Since that time 42 other petitions have been presented. It is evident, therefore, that the introduction of this Bill has not been regarded with indifference by the pharmacists of Great Britain, and that there is considerable unanimity of opinion among them that its provisions are fraught with danger to the objects which they have for years been striving to secure. That the representation of this opinion in Parliament, when the Bill comes under consideration, should be disregarded, is a proceeding that can scarcely be accepted as probable.

However, a medical contemporary in writing upon this subject expresses the opposite opinion, and undertakes to "imagine such petitions will receive little consideration from Parliament." That the ground for such an "imagination" consists only in misconception is, however, sufficiently evident from the remarks that accompany it. In the first place our contemporary's want of accurate acquaintance with the facts of the case is evident from the statement put forward that British pharmacists have simply been petitioning for protection against trade competition and have for that reason taken up a "mad-dog" cry against Irish pharmacists. If this were the case, we admit there would be ample justification for any disregard that Parliament might manifest towards the petitions against the Irish Pharmacy Bill. But there is not the shadow of a pretext for the statement made by our contemporary. The competition of Irish pharmacists is not what is feared or deprecated; for those who are entitled to that designation and legally privileged to carry on business as pharmacists are too few in number to admit of any apprehension that they would join in the invasion of their British brethren. It is in fact one of the main arguments put forward by those who support the institution of a Pharmaceutical Society in Ireland, that there are so few qualified pharmacists in Ireland, and that great inconvenience to the public arises from the deficiency. Moreover it must be remembered that every one of the legally qualified pharmacists in Ireland is, and always has been, entitled, in virtue of being an "apothecary," to carry on the business of pharmacy in Great Britain independently of the Pharmacy Act, 1868.

But what is feared as a possible result of the Irish Pharmacy Bill becoming law is, that persons of inferior qualifications would be brought into competition with British pharmacists. The establishment of an Irish Pharmaceutical Society, empowered to grant certificates entitling the holders of them to registration in Great Britain as pharmaceutical chemists, without giving the Pharmaceutical Society of Great Britain due control over the examinations conducted in Ireland, might well result in the flooding of this country with persons wholly unfit to assume the position of "pharmaceutical chemist."

To show that there is sufficient reason for apprehension of such a result we need only refer to the evidence given before the Select Committee on the Apothecaries' Licences Bill of last session. In reply to a question put by the Chairman, Sir MICHAEL HICKS-BEACH, whether there was not throughout Ireland a great deficiency of establishments and shops for the sale of medicine and compounding of prescriptions, resulting in great inconvenience to the public, Dr. LEET, the Secretary to the Apothecaries' Hall of Dublin, stated that such was the case. Sir DOMINIC CORRIGAN and other witnesses agreed with him in this. But it was also stated by Dr. LEET that this want existed especially in the rural districts and in small towns where apothecaries "could not live," and that the class of persons suitable for supplying this want would be such as would take up any branch of trade that would maintain them in such places. This in fact, was Dr. LEET's idea of a "pharmaceutical chemist" according to his evidence. Mr. COLLINS, a director of the Apothecaries' Hall, also stated that while the towns are at present overstocked with "apothecaries" qualified to practice pharmacy, the "pharmaceutical chemist" could not live in the places where he was wanted by pharmacy alone, but must sell drugs, oils, and probably tobacco, tea, and sugar.

If the object of the Irish Pharmacy Bill be to create a class of persons to occupy a position of this kind in Ireland, it is not a very great stretch of imagination to suppose that the evidence of qualification required of them by the Examining Board of the proposed Irish Pharmaceutical Society would not be of a very high standard. And when it is proposed to appropriate for these persons the title "pharmaceutical chemist," and to give them the right of claiming registration as such in Great Britain, it surely must be obvious to the most ordinary mind that such a proceeding is calculated to excite indignation amongst those who for years past have laboured to make the title of pharmaceutical chemist respectable in the eyes of the public, and an object of emulation to the followers of pharmacy.

It is this injustice that the pharmacists of Great Britain protest against; and it is on this ground that the Bill has been opposed by the Pharmaceutical Society. It is entirely erroneous to say that the Society "goes simply for securing the control of Irish pharmacy." On the contrary, the Society has always judiciously abstained from any attempt to interfere with the regulation of pharmacy in Ireland. The proposal to extend the Act of 1868 to Ireland did not emanate from the Society, but was made independently of it. The evidence given by members of the Council before the Special Committee last session was throughout of the same tendency. The Bill then under consideration was drafted by the King and Queen's College of Physicians, and in effect, it proposed to extend the operation of the British Society to Ireland, with a local Board of Examiners in Dublin under its control. This was felt to be a reasonable project, and one that the Society had no right to object to. Both Mr. Sandford and Mr. Mackay expressed their opinion that the plan would work as well in Ireland as it had done in Scotland, and it has always seemed unaccountable that the report of the Committee should have so thoroughly ignored and run counter to the evidence given, as to recommend that the Bill should not be proceeded with.

If, however, the prevalence of Home Rule ideas renders such an extension of the Society's operations undesirable, the Society has certainly no disposition to seek for it, and it has always admitted that if the present Bill had merely proposed to create a society for Ireland, with its operations limited in sphere and effect to Ireland, for maintaining or creating there a body of examined persons to be described otherwise than by the title of "pharmaceutical chemist," the Society could not have raised objection, but might eventually have seen its way to friendly co-operation whenever the contemplated society had acquired a standing comparable with its own public estimation.

Some attempt has been made by the advocates of the Bill now before Parliament, to turn to account the differences of opinion expressed at the last meeting of the Council, which is even asserted to be the arena of intestine war in reference to the subject. We do not hesitate to contradict this statement, and to declare that the difference of opinion expressed had reference only to a technical point. The objection to the provision for reciprocity without any concomitant control of the examinations was unanimous, and the only question was whether opposition should be specially directed to that point or against the Bill as a whole. One of the reasons for adopting the latter course was the appropriation of the title of pharmaceutical chemist as being not only an interference with the British Society, but also unnecessary for the purposes of the Irish Bill. All that is requisite in Ireland is a distinctive title by which the public may readily distinguish the pharmacist qualified to dispense physicians' prescriptions from the chemist and druggist who is not permitted to dispense. For this purpose the designation "dispensing chemist" would suffice perfectly, and it has even the advantage of being more explicit than the term "pharmaceutical chemist."

We are glad, however, to be able to state that within the last few days some disposition to compromise has been manifested on the part of the Government, and, as we are informed, the withdrawal of the reciprocity clause (18) has been suggested in consideration of a withdrawal of the Society's opposition to the Bill. So far as we can judge an arrangement of this kind, if thoroughly carried out, might be satisfactory to all parties, and leave our Irish neighbours free to establish an entirely independent pharmaceutical society adapted to their own ideas and requirements.

Such independence, however, must be, in every respect, thorough and not merely one-sided. We think, therefore, that in the event of any such settlement of the matter as that we have mentioned as being probable, and in case the objection to the title "pharmaceutical chemist" should be waived, adequate provision should, at least, be made for protecting British Pharmaceutical Chemists from any possible improper use of that title on the ground of certificates obtained from the Irish Society. For this purpose a clause like the 27th clause of the Pharmacy Act, 1868, might be appropriate, providing that "This Act shall not extend to *Great Britain*," or some other provision that would prevent the Irish qualification being used in the way that bogus degrees are often used with impunity.

MEETING OF THE MEDICAL COUNCIL.

The General Medical Council was to meet on Thursday, the 17th. inst., under the presidency of Dr. Acland, at the new offices, formerly the Royal College of Chemistry, Oxford Street.

THE FATAL EXPLOSION IN IRELAND.

The amount of compensation to be paid by the Governors and Directors of the Apothecaries' Hall, Dublin, in the case where death resulted from an explosion caused by the substitution of sulphide of antimony for oxide of manganese (see before, p. 823), appears to have been settled at £1500. That sum had been paid in to the Irish Court of Queen's Bench in satisfaction of the claim, and a motion has recently been made and granted for its withdrawal.

LIEBIG'S SUCCESSOR AT MUNICH.

The *British Medical Journal* states that the chair of Chemistry at Munich, which has remained vacant since the death of Liebig, has been accepted by Professor Baeyer of Strassburg, who will commence his duties next winter session.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

June 16*th*, 1875.

Present—Messrs. Allchin, Barnes, Carteighe, Corder, Gale, Haselden, Hills, Linford, Martindale, Moss, Schweitzer, Southall, Taylor, and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MAJOR EXAMINATION.

Three candidates were examined. *Two* failed. The following passed, and was declared qualified to be registered as a Pharmaceutical Chemist :—

Naylor, William Arthur Harrison. Manchester.

MINOR EXAMINATION.

Thirteen candidates were examined. *Nine* failed. The following *four* passed, and were declared qualified to be registered as Chemists and Druggists :—

Equal { Beilby, Alfred Emanuel ....Sutton-in-Ashfield.
Equal { Ragg, William Watkins.........Edmonton Green.
Neale, Edgar.........................Faringdon.
Wright, Alfred.......................Stowmarket.

The above names are arranged in order of merit.

BENEVOLENT FUND.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture VI.

Physical deterioration from Alcohol, continued. Influence on the vital organs. Mental phenomena induced by its use. Summary.

(*Continued from page* 999.)

Alcoholic Insomnia or Sleeplessness.

Lastly on this head, the perverted state of the vessels of the brain itself, the unnatural tension to which they are subjected from the stroke of the heart, which they are so incompetent to resist, sets up in the end one telling, and of all I have yet named most serious phenomenon, I mean *insomnia*, inability to partake of natural sleep. There is a theory held by some physiologists that sleep is induced by the natural contraction of the minute vessels of the

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts.*

brain, and by the extrusion, through that contraction, of the blood from the brain. I am myself inclined, for reasons I need not wait to specify now, to consider this theory incorrect; but it is nevertheless true that during natural sleep the brain is receiving a reduced supply of blood; that when the vessels are filled with blood without extreme distension, the brain remains awake, and that when the vessels are engorged and over-distended, there is induced an insensibility which is not natural sleep, but which partakes of the nature of apoplexy. This sleep is attended with long and embarrassed breathing, blowing expirations, deep snoring inspirations, and uneasy movements of the body, with even convulsive motion, and from it the apparent sleeper wakes unrefreshed and unready for the labours of the day. The effect of alcohol, then, on the brain, is to maintain the relaxation of vessels, to keep the brain charged with blood, and so to hold back the natural repose. Under such form of divergence from the natural life, the sleepless man lies struggling with unruly and unconnected trains of thought. He tries to force sleep by suppressing with a great effort all thought, but in an instant wakes again. At last the more he tries the less he succeeds, until the morning dawns. By that long time the spirit that kept his cerebral vessels disabled and his heart in wild unrest having become eliminated, he is set free, and the coveted sleep follows. Or perhaps wearied of waiting for the normal results, he rises, and with an additional dose of the great disturber, or with some other tempting narcotic drug of kindred nature, such as chloral, he so intensifies the vascular paralysis as to plunge himself into the oblivion of congestion, with those attendant apoplectic phenomena, which he himself hears not, but which, to those who do hear, are alarming in what they forbode, when their full meaning is appreciated. Connected with this sleep there is engendered in some persons a form of true epilepsy, which all the skill of physic is hopeless to cure, until the cause is revealed and removed.

And now I think I have said everything that I have time to say respecting the general phenomena incident to this primary stage of slow alcoholic intoxication in those who in the world's eye, as well as in their own, are temperate individuals—individuals who enjoy the choice things of this life heartily; who understand a glass of wine, and who can take a good many glasses—or a good many little "goes" of spirit if that be all—but who are never known by friend or foe to be worse for anything they take; who grow mellow as an apple under the mellowing cheer, but never fall, or lose their power of taking less guarded companions safely home.

Organic Deteriorations.

The continuance of the effects of alcohol into a more advanced stage leads to direct disorganization of vital structures. When once this stage has been reached not one organ of the body escapes the ravage. According to the build or the hereditary construction of the individual, however, or according sometimes to what may be considered as a local accident, some particular organ undergoes a change which gives a specific character to the whole of the phenomena that are afterwards presented. We then say of the person in whom such change occurs that he is afflicted with such a particular disease, letting the general sink into the local manifestation. Many purely local modifications of structures and parts are in this manner induced in the blood; in the minute structure of the moving organs—the muscles; in the fixed vital organs, such as the brain, the lungs, the liver, the heart, the kidneys. In the blood the influence is exerted upon the plastic fibrine and upon the corpuscles, in the brain, on the membranes at first, and afterwards on the nervous matter they enclose; in the lungs, on the elastic, spongy, connective tissue, which is, strictly speaking, also membranous; in the heart, on its muscular elements and membranes; in the liver, primarily on its membranes; in the kidneys, on their connective tissues and membranes.

Special Structural Deteriorations.

The organ of the body that perhaps the most frequently undergoes structural changes from alcohol is the *liver*. The capacity of this organ for holding active substances in its cellular parts is one of its marked physiological distinctions. In instances of poisoning by arsenic, antimony, strychnine, and other poisonous compounds, we turn to the liver, in conducting our analysis, as if it were the central depôt of the foreign matter. It is, practically, the same in alcohol. The liver of the confirmed alcoholic is probably never free from the influence of the poison; it is too often saturated with it.

The effect of the alcohol upon the liver is upon the minute membranes or capsular structure of the organ upon which it acts to prevent the proper dialysis and free secretion. The organ at first becomes large from the distention of its vessels, the surcharge of fluid matter, and the thickening of tissue. After a time there follow contraction of membrane, and slow shrinking of the whole mass of the organ in its cellular parts. Then the shrunken, hardened, roughened mass is said to be "hob-nailed," a common but expressive term. By the time this change occurs, the body of him in whom it is developed is usually dropsical in its lower parts, owing to the obstruction offered to the returning blood by the veins, and his fate is sealed.

Now and then, in the progress to this extreme change and deterioration of tissue, there are intermediate changes. From the blood, rendered preternaturally fluid by the alcohol, there may transude, through the investing membrane, plastic matter which may remain, interfering with natural function, if not creating active mischief. Again, under an increase of fatty substance in the body, the structure of the liver may be charged with fatty cells, and undergo what is technically designated fatty degeneration. I touch with the lightest hand upon these deteriorations, and I omit many others. My object is gained if I but impress you with the serious nature of the changes that, in this one organ alone, follow an excessive use of alcohol.

In the course of the early stages of deterioration of function of the liver from organic change of structure, another phenomenon, leading speedily to a fatal termination, is sometimes induced. This new malady is called diabetes, and consists in the formation in enormous quantity within the body of glucose or grape sugar, which substance has to be eliminated by dialysis, through the kidneys—a fatal elimination. The injury causing this disease through the action of alcohol may possibly be traced back to an influence upon the nervous matter; but the appearance of the phenomenon is coincident with the derangement of the liver, and I therefore refer to it in this place.

The *kidney*, in like manner with the liver, suffers deterioration of structure from the continued influence of alcoholic spirit. Its minute structure undergoes fatty modifications; its vessels lose their due elasticity and power of contraction; or its membranes permit to pass through them that colloidal part of the blood which is known as albumen. This condition reached, the body loses in power as if it were being gradually drained even of its blood. For this colloidal albumen is the primitively dissolved fluid out of which all the other tissues are by dialytical processes to be elaborated. In its natural destination it has to pass into and constitute every colloidal part.

The *lungs* do not escape the evil influence that follows the persistent use of alcohol. They, indeed, probably suffer more than we at present know from the acute evils imposed by this agent. The vessels of the lungs are easily relaxed by alcohol; and as they, of all parts, are most exposed to vicissitudes of heat and cold, they are readily congested when, paralysed by the spirit, they are subjected to the effects of a sudden fall of atmospheric temperature. Thus, the suddenly fatal congestions of lungs which so readily befall the confirmed alcoholic during severe winter seasons.

Alcoholic Phthisis, or the Consumption of Drunkards.

There are yet other and more prolonged, and more certainly fatal mischiefs induced in the lungs by the persistent resort to alcohol; and to one of these I would direct special attention. It is that deterioration of lung tissue to which, in the year 1864, I gave originally the name of *alcoholic phthisis*, or the *consumption of drunkards*. The facts came before me at first in this manner. In a public hospital to which I acted as physician, I had brought before me, in the course of many years, two thousand persons who were suffering from consumption. I gathered the history of the lives of these, and of the reasons why they had passed into the all but hopeless malady from which they suffered. In my analysis of these histories I found that the causes of the malady altogether were, in the great majority of instances, predisposition from hereditary taint; exposure to impure air; want; or certain other allied causes. But the analysis being conducted rigidly, I discovered that, when every individual instance had been classified as due to the causes stated above, there remained thirty-six persons, or nearly two per cent. who were excluded from them, who appeared to suffer purely from the effects of alcohol, and in whom the consumption had been brought into existence by the use of alcohol.

The added observations of eleven years, since the abovenamed fact was recorded in the *Social Science Review*, as a new fact in the history of the disease, have only served to prove, in the minds of other men as well as my own, the truth of the record.

The persons who succumb to this deterioration of structure induced by alcohol, are not the exceedingly young, neither are they the old. They are usually over twenty-eight and under fifty-five. The average age may be taken as forty-eight. They are persons of whom it is never expected that their death will be from consumption; they are generally males. They are probably considered very healthy;—men who can endure anything, sit up late at night, run the extreme of amusements, and yet get through a large amount of business. They sleep well, eat pretty well, and drink very well. They are often men of excellent build of body, and of active minds and habits. They are not a class of drinkers of strong drinks, who sleep long, take little exercise, and grow heavy, waxy, pale—

"Sleek-headed men and such as sleep o'nights."

On the contrary they take moderate rest, and see as much as they can. Neither in the ordinary sense are they drunkards: they may never have been intoxicated in the whole course of their lives; but they partake freely of any and every alcoholic drink that comes in their way, and they bear alcohol with a tolerance that is remarkable to observers. They are hard drinkers as distinguished from sots. Beer is to them as water, wine is weak; the only thing that upsets them is stiff grog in relays, or a mixture of spirituous drinks carried to the extent of what they call in grim joke—in which death surely joins—"piling up the agony."

As a rule these cannot live in what they consider to be comfort without a daily excess of alcohol, which excess must needs be renewed on emergencies, if there be greater amount of work to be done, less sleep to be secured, or more life to be lived.

As specimens of animal build these persons are often models of organic symmetry and power. In fact they resist the enemy they court for so long a time because of the perfection of their organization. More than half of those whom I have seen stricken down with alcoholic phthisis have said that they never had a day's illness in their lives before: but questioned closely it was found that none of them had actually been quite well. Some of them had suffered from gout; others from rheumatism or neuralgia. They had felt severely any depression, such as that which arises from a cold, and if they had been subjected suddenly to causes of excitement or exhaustion, they had detected without actually realizing its full meaning, that their balance of power against weakness was reduced, that the end of the beam called strength was rising, and that an extra quantity of alcohol was required to bring back equilibrium. As a rule men of this class are thoughtless of their own health and their own prospects, for they have an abundant original store of energy. They are designated as "happy-go-lucky" men, or as men who "always fall on their feet," which truly they do, but not without injury.

The countenance of the alcoholic consumptive differs from that which is usually considered the countenance of the consumptive person, and equally from that which all the world adjudges as belonging to the man who indulges freely in strong drink. Who does not remember the wan, pale, sunken cheek of the youth on whom ordinary consumption has set its mark? And who, again, does not recall the *facies alcoholica*—the blotched skin, the purple red nose, the dull, protruding eye, the vacant stare of the confirmed sot? The alcoholic consumptive has none of these characteristics. His face is the best part of him in all his history. When his muscles have lost their power, and his clothes hang loosely on his shrunken limbs, he is still of fair proportion in the face; he has little pallor, and he is expressive of feature, so that his friends are apt to be deceived and to believe that there must be hope for his recovery, even when he is beyond every hope. I remember being actually taken aback on one occasion on finding, in a man who seemed, from his face, to be in perfect health, how completely destroyed his lungs were by the encroachments of disease; and I cannot be surprised, therefore, that others, less informed, should share in such an imperception of danger when it is close at hand. Nobody, in a word "pities the looks" of these sufferers, and good eyes are necessary to learn that pity is called for.

The phenomena are not always developed at a time when the sufferer from them is indulging most freely in alcohol. On the contrary, it is by no means uncommon that the habit of excessive indulgence has been stopped for some time previously to their development. The reasons assigned by the patients for abstinence vary. One man may have been strongly advised by his friends to desist, or may himself have undergone a certain measure of reform; another has been led by the reading or hearing of arguments on temperance; a third, by want of means to obtain the indulgence; but by far the larger number tell you that a time came when the desire for so much drink did not occur to them. They will state that they tried the round of the various spirits, but found that none agreed with them as before, so that at last they were driven to rely on beer as the only drink they cared for. We read all this off clearly enough from a physiological point of view. We see that, in fact, the body has been resisting the alcohol; that it could not do away with it as it did when all the excreting organs were in their full prime; and that those drinks only can be borne in which the amount of alcohol is least, but the sufferer does not comprehend the fact, and therefore he not unfrequently concludes that his increasing langour and debility are due to the necessary withdrawal of the stimulus on which he seems to have been actually feeding during the greater part of his life.

The signs which first indicate failure of health are usually those of acute pleurisy. There is pain in the side, quick, sharp, startling. The term "stitch" in the side is commonly applied to this pain, and is expressive enough. After a time the pain becomes continuous, and when it subsides, suppressed breathing, or difficulty of filling the chest, is at once felt and recognized. This difficulty is due to the circumstance that a portion of lung has become adherent to the inner surface of the chest. The next sign indicating that the disease (consumption) is present, is, usually, vomiting of blood. In two-thirds of the examples to which my attention has been directed this has been the sign that has first caused serious alarm. It is commonly on this event that the physician is called in, who examines the chest with the stethoscope, and finds too often a condition that is hopeless. From the appearance of that sign all is—down, down, down towards the grave.

There is no form of consumption so fatal as that from alcohol. Medicines affect the disease but little, the most judicious diet fails, and change of air accomplishes but slight real good. The sick man with this consumption may linger longer on the highway to dissolution than does his younger companion, but there is this difference between them, that the younger companion does often leave the highway to find a by-path to health, while the other never leaves it, but struggles on straight to the end. In plain terms, there is no remedy whatever for alcoholic phthisis. It may be delayed in its course, but it is never cured, and not unfrequently instead of being delayed it runs on to a fatal termination more rapidly than is common in any other type of the disorder.

The origin of this series of changes from alcohol is, as you will perceive, again on the membranes. The course of it is through the membranous tissues. The vessels give way after a severe congestive condition, and blood is exuded, or extravasated into the lung.

Alcoholic Disease of the Heart.

The heart, not less than the rest of the vital parts, is subjected to deterioration of structure from alcohol. We need not wonder at this when we recall the strain to which it is subjected by the agent, the excess of work it is made to perform. I touched on the mechanical evils that befell the heart from these circumstances in my last lecture, and the structural evils which I have now to specify are not less grave. The membranous structures which envelop and line the organ are changed in quality, are thickened, rendered cartilaginous, and even calcareous or bony. Then the valves, which are made up of folds of membrane, lose their suppleness, and what is called valvular disease is permanently established. The coats of the great blood-vessel leading from the heart, the aorta, share not unfrequently in the same changes of structure, so that the vessel loses its elasticity and its power to feed the heart by the recoil from its distention, after the heart, by its stroke, has filled it with blood.

Again, the muscular structure of the heart fails, owing to degenerative changes in its tissue. The elements of the muscular fibre are replaced by fatty cells; or if not so replaced are themselves transferred into a modified muscular texture in which the power of contraction is greatly reduced.

Those who suffer from these organic deteriorations of the central and governing organ of the circulation of the blood learn the fact so insidiously, it hardly breaks upon them until the mischief is far advanced. They are for years conscious of a central failure of power from slight causes, such as over-exertion, trouble, broken rest, or too long abstinence from food. They feel what they call "a sinking," but they know that wine or some other stimulant will at once relieve the sensation. Thus they seek to relieve it until at last they discover that the remedy fails. The jaded, over-worked, faithful heart will bear no more; it has run its course, and—the governor of the blood stream broken—the current either overflows into the tissues, gradually damming up the courses, or under some slight shock or excess of motion ceases at the centre.

(To be continued.)

QUEBEC PHARMACEUTICAL ASSOCIATION.

The Pharmaceutical Association of Quebec has now appointed the first Board of Examiners under the Pharmacy Act recently passed for that province. The examiners are Messrs. Nathan Mercer, Alexander Manson, W. E. Brunet, Henry R. Gray, J. D. L. Ambrose, H. F. Jackson, and Henry Lyman.

Parliamentary and Law Proceedings.

Pharmacy Act (Ireland) Bill.

The second reading of this Bill has been postponed from Monday, June 14, to Friday, June 20.

In the House of Commons on Monday, June 14, in answer to Dr. Playfair,

Sir M. Hicks-Beach stated that there were very few licentiates of the Apothecaries' Hall in Ireland who restricted themselves to pharmacy, and that there was no other class of chemists and druggists in that country who could legally dispense medicine according to prescription.

Since the publication of the list on p. 1000, the following petitions against the Bill have been presented. Only one petition, that from the King and Queen's College of Physicians, has yet been presented in its favour:—

Aberdeen	Mr. John Farley Leith.
Andover	Rt. Hon. Dr. Lyon Playfair.
Atherstone	Mr. C. Newdigate Newdegate.
Bangor	„ William Bulkley Hughes.
Bodmin	Hon. Edward F. Leveson Gower.
Boston	Mr. John Wingfield Malcolm.
Bradford	„ Henry William Ripley.
Brecon	Rt. Hon. Dr. Lyon Playfair.
Bridlington	Mr. Christopher Sykes.
Cambridge	„ Alfred George Marten.
Chelsea	Rt. Hon. Dr. Lyon Playfair.
Christchurch	Sir H. Drummond Wolff.
Diss	Sir Robert Jacob Buxton, Bt.
Dudley	Mr. Henry Brinsley Sheridan.
Eastbourne	„ George Burrow Gregory.
Finsbury	Sir Andrew Lusk, Bt.
Flint	Mr. Peter Ellis Eyton.
Hackney	Rt. Hon. Dr. Lyon Playfair.
Helston	Mr. Adolphus M. Young.
Inverness	„ Charles Fraser Mackintosh.
Kilmarnock	„ J. Fortescue Harrison.
Lambeth	Rt. Hon. Dr. Lyon Playfair.
Liverpool	Mr. John Torr.
London	Alderman W. J. R. Cotton.
Lymington	Lt. Col. Edmund H. Kennard.
Maidenhead	Lt.-Col. Robert J. Lloyd Lindsay.
Maidstone	Rt. Hon. Dr. Lyon Playfair.
Malmesbury	Rt. Hon. Dr. Lyon Playfair.
Marylebone (3)	Mr. William Forsyth.
Nuneaton	„ C. Newdigate Newdegate.
Paisley	„ William Holms.
Penrith	„ Wm. Nicholson Hodgson.
Portobello and Musselburgh	„ Donald R. Macgregor.
Ramsgate	„ Edward Leigh Pemberton.
Retford	Viscount Galway.
Rugby	Mr. C. Newdigate Newdegate.
St. Albans	„ Thomas Frederick Halsey.
Shoreham, New	Sir Percy Burrell, Bt.
Southwark	Colonel F. Marcus Beresford.
Stockton-on-Tees	Mr. Joseph Dodds.
Stourbridge	Rt. Hon. Dr. Lyon Playfair.
Tavistock	Rt. Hon. Dr. Lyon Playfair.
Teignmouth	Sir. Lawrence Palk, Bt.
Tower Hamlets	Mr. Joseph D'Aguila Samuda.
Tunbridge Wells	„ William Hart Dyke.
Wareham	„ John S. W. S. E. Drax.
Wednesbury	„ Alexander Brogden.
Wellington	Lt.-Col. Hon. A. W. N. Hood.
West Hartlepool	Mr. Thomas Richardson.
Westminster	Rt. Hon. Dr. Lyon Playfair.
Woodstock	Rt. Hon. Dr. Lyon Playfair.
Wrexham	Mr. George Osborne Morgan.

Petitions were also presented from the following places:—

Leek.	St. Andrews.
Margate.	St. Leonards.
Newtown.	Stoke-on-Trent.
Preston.	Whitby.

The Drugging of Animals Bill.

The second reading of this Bill, which had been deferred on Monday the 14th inst. until Wednesday the 16th, was on that date again postponed until Friday the 18th inst.

Sale of Food and Drugs Bill.

On Tuesday, the House of Lords went into Committee on this Bill.

Clauses 1 and 2 were agreed to.

On Clause 3,

The Earl of Morley moved the omission of the word "knowingly," the retention of which would, in his opinion, greatly mar the utility of the measure. How could it be proved—as it must be before a conviction could be obtained under the Bill if it became law as it stood—that a trader knew he was selling adulterated drugs or food? He believed that druggists, at all events, were perfectly competent of being aware of the quality of what they were selling. They either mixed the articles they sold for themselves or they obtained them mixed from others, and in the latter case they had a remedy against the person they purchased from under Clause 5. He had no desire to harass traders or to place undue restrictions upon trade; but to secure that the Bill should operate beneficially, he hoped the word "knowingly" would be omitted from the clause.

The Duke of Richmond said the effect of the noble earl's amendment would be to render every trader who sold adulterated drugs or food, however ignorant he might be of the fact, liable to be imprisoned for a period not exceeding six months with hard labour. A man might be perfectly innocent, and have nothing whatever to do with the articles he sold save to sell them, and yet he would be liable to imprisonment. The clause was substantially the same as that in the Act of 1872, so that the proposed legislation was not new, but proceeded on the basis of the old. He should be sorry to omit the word "knowingly," as he believed that great injustice might ensue if it were struck out.

Earl Fortescue thought that the onus should be thrown on the trader of proving his ignorance, as it would be most difficult in the case of a prosecution to prove guilty knowledge.

The Lord Chancellor said that the noble lord proposed that the question of knowledge should not enter into the offence. The Act would, therefore, impose a penalty of £50 upon a tradesman who sold a mixed article, whether he knew it to be mixed or not? Was that justice? A suggestion had been made that the onus ought to be changed, and that it should be assumed that a man was guilty until he had proved that he was innocent. In that case, however, the mouth would be stopped of the person who could give the best evidence—namely, the accused himself, and thus while there was a fair chance that the prosecutor would offer presumptive evidence in favour of a conviction, there would be no opportunity on the part of the person accused of proving his innocence.

After a short conversation their lordships divided, when there appeared for the clause:—Contents, 41; Not Contents, 23; Majority, 18.

The clause was then ordered to stand part of the Bill.

Clause 4 was also agreed to.

On Clause 5,

The Duke of Richmond said he proposed to strike out the proviso introduced in the third reading of the Bill in the House of Commons, that if a retail dealer who was fined had sold an article in the condition in which it was supplied to him by the wholesale dealer he should have a right of action against such wholesale dealer for the recovery of the penalty and costs. It seemed to him that the proviso did not afford the remedy which was intended in the case it was desired to meet, and that this could be done best in Clause 24, which provided for the acquittal of the retail dealer if he had purchased from the wholesale dealer with a written warranty.

The Earl of Morley approved the change, and remarked that at present the retail dealer was under no obligation to prosecute. It ought to be clearly understood that there was to be a prosecution of the wholesale dealer if he were to blame.

The proviso was struck out, and Clauses 5, 6, 7 and 8 were agreed to.

On Clause 9, which refers to the appointment of analysts,

The Earl of Morley urged that the appointment of analysts ought to be made compulsory, and not left optional with local authorities. Appointments had been made already in 32 out of 54 counties, and in 126 out of 171 boroughs. If the Act had done good in some places it would do good in others; and it was desirable that there should be uniformity in the administration of the law, or else adulterated articles would certainly find their way into places where no analysts had been appointed. No doubt there might be a difficulty in finding analysts, but that could be partly met by the combination of authorities and the making of appointments for larger areas, and by boroughs accepting the analysts appointed by the county authorities. Essex, Kent, and Sussex had appointed analysts in London. Up to the present time he believed the Local Government Board had not exercised the power conferred upon them to compel a local authority to appoint an analyst.

The Duke of Richmond could not assent to the suggestion. The Local Government Board already had the power to compel where they thought fit, and it might be presumed they would exercise that power where they thought it necessary. It was not desirable to make appointments more compulsory than they were at present, and there were practical difficulties in the way of boroughs combining with counties and counties combining with each other, for there was no machinery to enable them to make the necessary apportionments of the salaries of the analysts.

The Duke of Somerset thought it very desirable that the analysts should submit to some regular examination before they were appointed. The Committee had made a recommendation to that effect.

The Duke of Richmond observed that the responsibility rested with the Local Government Board, and no doubt they would satisfy themselves as to the qualifications of the analysts before they sanctioned their appointment.

Lord Aberdare suggested that, instead of "may," the word "shall" be inserted in the clause, which would go far to secure the appointment of properly-qualified analysts. The Home Office could not appoint an Inspector of Mines without his undergoing an examination.

The Duke of Somerset read an extract from the evidence given before the Committee to show that there would be no difficulty in having an examination at South Kensington. People would have more confidence in the analysts if they knew that they had been regularly examined. It would also tend to greater uniformity of opinion as to what should be considered adulteration if they passed a uniform examination.

The Earl of Morley said it was distinctly recommended by the Select Committee that the appointment of an analyst should be compulsory, and he therefore moved the substitution of the word "shall" for "may," in line 41, page 3, to carry out that object.

The amendment was negatived.

The Duke of Somerset then moved, in line 11, page 4, in the same clause, that the word "may" should be struck out and "shall" inserted before the words "require satisfactory proof of competency." The clause as it stood provided that the Local Government Board, to whose approval the appointment of the analyst was to be subject, might require satisfactory proof of the competency of the person appointed. He thought they ought to be bound to require such proof, and therefore he proposed that amendment.

The Duke of Richmond opposed the amendment, thinking they ought to place confidence in the public department, which could be trusted to see that there was satisfactory proof of competency in those cases.

After some conversation the amendment was negatived and the clause was then agreed to.

On Clause 27,

The Duke of Richmond moved that the following proviso be added:—

"Provided that in any action brought by any person for a breach of contract on the sale of any article of food or of any drug, such person may recover alone or in addition to any other damages recoverable by him the amount of any penalty in which he may have been convicted under this Act, together with the costs paid by him upon such conviction, and those incurred by him in and about his defence thereto, if he prove that the article or drug the subject of such conviction was sold to him as and for an article or drug of the same nature, substance, and quality as that which was demanded of him, and that he purchased it not knowing it to be otherwise, and afterwards sold it in the same state in which he purchased it; the defendant in such action being, nevertheless, at liberty to prove that the conviction was wrongful, or that the amount of costs awarded or claimed was unreasonable."

The motion was agreed to.

On Clause 29, which provided that tea should be examined by the Customs officers on importation,

Lord Cottesloe moved that it should be omitted, because it would be impossible for the Customs Department, with its present strength, to perform the task which the clause imposed upon it, and because there was ample reason to expect that the trading community itself would provide satisfactorily for the examination.

The Duke of Richmond regretted that he could not accept the amendment proposed by the noble lord. The committee which had sat to consider this question had recommended that the examination of the tea should be conducted by the Customs on its arrival in this country, so as to put an end to the practice of adulterating tea which prevailed in China. He had been informed by the Custom-house authorities that the examination of the tea could be made by the Custom-house officers without difficulty. The effect of the clause would be to benefit the consumer and to protect the retail dealers in this country.

The Marquis of Lansdowne viewed with some apprehension the introduction by this clause of the principle that the mere lodging merchandise in the Custom-house was a guarantee of its purity.

Lord Stanley of Alderley was of opinion that the effect of the clause would be to prevent bad teas being shipped from China.

The amendment was negatived, and the clause having been agreed to, the Bill passed through Committee.

Review.

The Chemistry of Light and Photography in its Application to Art, Science, and Industry. By Dr. Hermann Vogel, Professor in the Royal Industrial Academy of Berlin. With one hundred illustrations. Henry S. King and Co., 65, Cornhill, and 12, Paternoster Row, London. 1875.

The international scientific series of Messrs. King and Co. is at once indication and evidence of a growing desire for information regarding matters which a few years ago were considered too abstract in their nature to be either interesting or useful to the mass of readers. Volumes comprised in the series have been previously reviewed in these pages, and generally in a favourable manner. Too much credit can scarcely be given to the respective authors for the skill which has avoided the Scylla of disgust at technicalities on the one hand, and the Charybdis of misinformation through a too diluted style, on the other. If there is any subject which more than another requires dexterous treatment in popularizing, it is applied chemistry, particularly if it be attempted to explain matters which are partly theoretical; indeed, if it is not practicable to impart a logical knowledge of the elements of the science, we are persuaded that it is better to refrain from such attempts and stick to mere facts. The volume before us is excellent for the information it gives on the origin and development of photography, from the time when it was first noticed that lunar caustic darkened in sunlight, to the present day when the productions of the art are fruitful in profit to many and in delight to all. Details of the different processes are given with a particularity almost sufficient to make a photographer of every reader, and we could wish that the author, who is quite at home here, had confined himself to this part of his subject. He attempts, however, to explain to lay readers, and in simple language, the chemical changes involved in working the processes, and we fear the result is worse than non-success. We know not on what hypothesis to account for it, whether it is that the author is writing in a tongue not his own, or that he is far less of a chemist than a photographer, or that he has been handicapped with a non-professional translator, but the language of these parts of his book reminds us very forcibly of the masticated lingo which nurses and fond mammas find the best medium for articulate communication with infants. To the tyro in chemistry it is simply ridiculous; often the statements are positively erroneous; the non-chemical reader would be much less instructed after perusal than if no such explanations were vouchsafed.

It is almost needless to say that the book is admirably got up. The illustrations comprise excellent impressions of electrotypes from heliographs, and two beautiful photographs—one of the moon and one showing the effect of retouching a negative.

The Potato Disease and the Curl Disease in Potatoes: their Causes and Prevention, with Strictures on the Potato Fungus (Peronospora infestans). By Eccles Haigh. London: G. Philp. 1875.

The Commercial Handbook of Chemical Analysis; or Practical Instructions for the Determination of the Intrinsic or Commercial Value of Substances used in Manufactures in Trades and in the Arts. By A. Normandy. New edition, enlarged and to a great extent rewritten. By Henry M. Noad, Ph. D., F.R.S. London: Lockwood and Co. 1875. From the Publishers.

Notes and Queries.

[441]. GINGERBREAD WORM NUTS.—Can any correspondent furnish a good form for Gingerbread Worm Nuts?—T. H. W.

PRESERVATION OF PASTE.—Mr. T. Stokoe writes:—"Though a small matter, it may be of service to some readers to know that the addition of 10 drops of common carbolic acid to a pint of flour paste, as soon as the boiling thereof is effected, will preserve it for, apparently, an indefinite time. I have just used some for labelling, which was made on May 5, and it is perfectly sweet and free from mould.

Obituary.

Notice has been received of the death of the following:—

On the 4th June, 1875, Mr. John E. H. Jennings, Pharmaceutical Chemist, of Sheffield, aged 61. Mr. Jennings had been a Member of the Pharmaceutical Society since 1844.

On the 9th June, 1875, Mr. Thomas James Smith, Pharmaceutical Chemist, of Newark, aged 23. Mr. Smith was a Member of the Pharmaceutical Society.

At the house of his brother, Alexander Gorrie, Chemist, Kirkcaldy, on the 9th inst., John P. Gorrie, Chemist and Druggist, 76, St. John Street, Perth, aged 26 years.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Drugging of Animals Bill.

Sir,—Your correspondent "From an Agricultural County" is quite right when he says some restriction should be put on the sale of nitrous acid, etc., and I am sure every member of our calling would agree with him if they knew, as we who carry on the drug trade in the country know, the extent to which "spicing" (as it is called) horses is carried. But it is no use passing stringent Acts to compel chemists to keep poisons books, etc., so long as little or no notice is taken of general shopkeepers in villages selling poisons. I know they cannot legally sell them, but the fact exists that they do, and I believe they are generally unaware that they are infringing the law.

Oil of vitriol is the favourite article with carters in my neighbourhood, and I make it a practice never to serve it or any other poison to a carter unless he produces an order from his master. When I have occasion to express this rule of mine, I am frequently told "Well it don't matter, I can get it at Mr. So and So's, only I thought yours might be stronger."

I for one shall hail with delight any enactment, let it entail what extra trouble it may, by way of registration of sales, etc., if the evil can be ended, and I trust sincerely Sir J. Astley will carry his Bill.

A Country Pharmaceutist.

The Major Qualification.

Sir,—It is very pleasant to hear of the existence of "T. T.," and indeed of any young man possessing his sentiments, but I fear that such are exceptions to the general rule, and hardly fair specimens of the pharmaceutical student. Would that they were! Anyhow, I congratulate Trowbridge, and only wish I could be convinced that I am wrong in my estimate of the class. They will certainly be rewarded by the acquisition of knowledge, and if their numbers sufficed for the support of the Society it would be neither necessary nor indeed desirable to run after those who lack the energy or inclination to secure for themselves the Major qualification on higher grounds than those of pecuniary advantage. That the "T. T.'s" are not in the majority seems however to be the complaint of the Council in their report, and hence my suggestion that in order to entice a greater number into the fold of Pharmaceutical Chemists, the distinctions betwixt the two grades should be made as clear as possible to the public by the simplification of pharmaceutical titles, and also the advisability of the rigid preservation of the few remaining privileges of that class.

As regards the best contraction for "Pharmaceutical Chemist," I may perhaps be here permitted to express my agreement with the opinion of Mr. Penney that "Ph.C." is preferable, and I merely followed the example of others in making use of the letters "P.C." What objection "An Old Chemist and Druggist" can have to any person, duly qualified, affixing the letters "Ph. C." or "P.C." or the words "Pharmaceutical Chemist" to his name (unless it is to be found in the fact of his being "An Old Chemist and Druggist" with a perhaps rather natural dislike for "new fangled titles") I cannot imagine, for it is most probable that he has "Chemist and Druggist" on his own labels, etc., and if so, why should not the Pharmaceutical Chemist be allowed to declare his trade in like manner, either in full or by means of the less cumbersome abbreviation. Whilst thanking him for the contributions to the facetiæ of the Journal, I fail to perceive any object in his letter except to prove, what I have always contended, that the letters "M.P.S." make a greater impression on the mind of the public than the more honourable title of "Pharmaceutical Chemist." In conclusion, I maintain that the Pharmaceutical Chemist's is a superior diploma to many of those foreign ones procured for a few shillings, or at most, pounds, which pass muster with thousands of the public and indeed place their proprietors on a level with others who have obtained the same titles after a protracted course of study at our own Universities or Colleges.

Urtica.

"*Beta Tau*"—(1) We do not quite understand your question. (2) It is no part of a chemist's business.

T. P. B.—No, the Pulv. Liquiritiæ comp. of the German Pharmacopœia contains sulphur and fennel. The formula is given on p. 660 of the present volume.

T. S. S.—Bentley and Redwood's 'Elements of Materia Medica' (Longmans), supplemented by Flückiger and Hanbury's Pharmacographia.'

G. W. W.—Yes, provided that you do not send any before you have done your utmost towards naming them correctly yourself.

F. E.—(1) Apply to the Secretary of the Royal College of Surgeons. (2 and 3) We possess no qualification for answering these questions.

"*Humilis.*"—We cannot do better than recommend you to study the opening sections of the book in which your difficulty occurs.

Oxon.—We cannot give you any information respecting the "origin" of the preparation mentioned. We are not aware that it is mentioned in any of the Continental pharmacopœias, or even that it took "its rise on the Continent."

"*Azote.*"—We presume that it would be.

R. B. H.—*Melilotus officinalis*, *Sherrardia arvensis*, *Sanicula europœa*, *Polygala vulgaris*. Bentham's 'Handbook' is a good one, but as many species of other authors are not distinguished therein it is useful to supplement it by such a manual as Babington's.

Cruciferæ.—*Rhinanthus Crista-galli.*

G. Watt.—(1) *Lychnis diurna.* (2) Probably *Galium saxatile.* (3) Probably *Fumaria muralis.* Nos. 2 and 3 must be sent in the fresh state, and in fruit for accurate determination. (4) Yes, *Lotus corniculatus.*

"*Alpha.*"—Yes, we think so.

"*Liebig.*"—(1) We are not aware that there is any patent for the preparation you mention, and if there be, the publication of a formula for such a preparation would be no infringement, neither would the use of such a formula, unless it were identical with that patented. (2) We are not aware of any special claim to the term "mustard leaves."

N. J. Lewis.—The only remedy we know of is to make the mixture fresh when it is wanted.

T. Robinson.—We believe that the poisonous ingredients are essential to the efficacy of the preparations.

J. Gray.—(*a*) *Vicia sepium*; (*b*) *Pedicularis sylvatica*; (*c*) *Lychnis diurna*; (*d*) *Trifolium minus*; (*e*) *Rumex acetosella*; (*f*) *Sison Amomum*; (*g*) *Ajuga reptans*; (*h*) *Veronica officinalis*; (*i*) *Lysimachia nemorum*; (*k*) *Polygala vulgaris*; (*m*) *Stellaria Holostea.*

E. T. Shaw.—See p. 421 of the present volume of this Journal.

A. H. P. is referred to the rule respecting anonymous communications.

E. Walsh.—We think the prefixing of your name to the title of the article would be held to imply an exclusive proprietary interest.

"*Preliminarian.*"—The information may be found in any good modern arithmetic book.

Communications, Letters, etc., have been received from Mr. A. Annette, Mr. A. P. Smith, Professor Flückiger, Messrs. Palmer and Howe, Antiseptic, A Country Druggist, G. T., G. F. K.

SOME RECENT IMPORTATIONS OF CINCHONA BARKS.

BY DAVID HOWARD, F.C.S.

The recent importations of cinchona bark from the East Indian plantations have afforded an opportunity of confirming an observation made by Dr. de Vrij (*Pharm. Journal*, 3rd series, iv., 869) of the presence of quinidine in the renewed bark of *C. succirubra*.

Samples of renewed bark have been received from three different plantations in the Neilgherries, and they all prove to contain quinidine in quantities of 0·1 to 0·2 per cent. The bark of the same species from the same plantations, grown either exposed or under moss, has in no case yielded this alkaloid when similarly tested.

It is most remarkable that the abnormal growth of the renewed bark should thus not only modify the proportions of the alkaloids found naturally in the bark, but develop another alkaloid that does not appear to exist naturally in this bark grown either in South America or in the East Indies—at any rate in appreciable quantities.

Another curious example of the effect of the circumstances of growth in modifying the production of this alkaloid is afforded by the *C. officinalis* of the same plantations; a sample of the root bark of this species gave as much as 0·8 per cent., while the stem bark of the same trees yielded only ·13 per cent.

It would have been very interesting to observe the effect of renewing the bark of the same trees from which this root bark was taken upon the production of quinidine; but, unfortunately, the experiment was not tried. A sample of renewed bark of *C. officinalis* from another plantation gave 0·2 per cent. of quinidine, the natural bark of the same plantation giving only 0·04; in this case the quinidine is increased, but not beyond the quantity found in some samples of natural crown bark.

It will be observed that both the renewed bark and the root bark show in their texture the signs of a somewhat analogous process of growth.

It is to be hoped that the influence of cultivation and of the circumstances of growth upon the development of the different alkaloids will receive all the careful study it deserves; it is evident that there is still much to be learned about this matter, and that much of the future success of the East Indian plantations depends upon careful chemical research.

SOME ADULTERATED GROUND GINGER.

BY HENRY POCKLINGTON, F.R.M.S.

The results of my recent inquiry into the genuineness of the ground pepper sold in a certain class of shops induced me to extend my inquiries further, and to test various other food accessories and food sold in the same shops.

The results are very similar to those previously described in this Journal,* and have confirmed me in the opinion that, in Leeds at all events, there is a vast amount of undetected systematic adulteration and that it is the poor who are the sufferers by it. It may, perhaps, beas well to say at once that I believe that the whole of the retailers of these adulterated articles have been innocent of all knowledge of the fraud. Here, as in most large towns, there are hundreds of small shops, dwelling-houses with a shop window and a small front room used as sale shop, and kept by the wives of mechanics and clerks with the evening assistance of their husbands, who, like themselves, are quite ignorant of the trade and entirely at the mercy of the wholesale dealer, who, possibly, himself is equally in the hands of the manufacturer.

It is against these small traders that the Adulteration Act has pressed heavily; but that they should therefore be relieved from its incidence is I think very questionable, since the non-trading public have a better right to be considered; it is, however, much too large a question to be answered or even discussed here. My object in writing these notes of certain adulterations detected is simply to call attention to the fact that there is, locally at all events, a considerable prevalence of adulteration; to put the readers of the Journal on their guard; and, as far as possible, place the means of its detection within their reach.

The first article with which I propose to deal is ground ginger. The adulteration of this is very extensive, as may be seen from the fact that five samples purchased in five shops taken seriatim on my road home one night were extensively adulterated, and that of several other samples examined, all but one, purchased in a first-class shop as an experiment, were also adulterated. These samples may be grouped in three classes, the adulterants of two of which are similar in nature to those found in the pepper previously described. There is no doubt that the adulterators are the same, and it is to be hoped that they may speedily receive the notoriety they deserve, or that, at all events, the excuse of ignorance may be taken from the wholesale and retail traders concerned.

The samples in class one were adulterated with small quantities of pea meal, large quantities of ground rice, a little wheat or barley starch and cheap damaged arrowroot. The total adulteration I estimate at 50 per cent., but in the case of ground ginger these estimates are at best but approximations more or less remote.

Class two comprises samples adulterated with ground rice, maize, and traces of other starches, but no pea meal.

The samples in class three were only two in number and were remarkable for the variety of starches they contained. They were evidently adulterated with sweepings, or a mixture of damaged arrowroot in addition to ground rice and a small quantity of what appears to be Rio arrowroot. One of these samples was given me by a pharmacist who said it was a portion of an old stock, the other was purchased in a very small shop where the sale of ground ginger must be extremely limited. The samples agreed in being heavily "limed," one contained a notable quantity of sand.

The microscopical examination of ground ginger is not very difficult, but requires the exercise of a considerable amount of care, as the starch granules of the ginger rhizome vary considerably in size and shape. With a view to rendering this article useful to such pharmacists as possess a microscope, I have had careful drawings made of the various forms assumed by ginger starch, and of a few of the more common adulterations. The drawings have been made to scale, excepting in one instance, the granules having

* *Pharm. Journ.* [3], vol. v., p. 681.

Fig. 1. Ginger starch.*

been immersed in water for a period not exceeding one hour. The power employed was $\frac{1}{5}$, giving with the eye-piece employed a power of 500.

It will be observed that the size of the granules varies considerably, but it may be noticed that in the oval granules the size of any of the numerous modifications of the oval is pretty constant. In other words, any change of shape is usually accompanied by variation in size. The size of the most commonly occurring granules, expressed in micrometric units (the most ready way for practical work, the value of the unit being stated) is as follows :—M (Jackson's micrometer, negative eye-piece and $\frac{1}{4}$ object glass) equals $\frac{1}{2100}$ of an inch. 2·5 × 1·75 ; 2 × 2 ; 2 × 1·5 ; 3 × 2 ; 2 × 1·5 ; 3·5 × 1·75 ; 2·5 × 2·5 ; 1 × 1. These are the measurements of a sample of fine Jamaica ginger. Samples of so-called African ginger furnish a starch whose granules, whilst they follow the same general characters as those of Jamaica ginger, have a larger average size, and granules of 3·75 × 2 are not uncommon.

The hilum and the concentric lines of ginger are very indistinct unless great care be taken to properly illuminate them, and it is very desirable to make use of a good achromatic condenser and radial stops.

The stellate hilum of Rio arrowroot is a striking feature in that starch, and at once distinguishes it

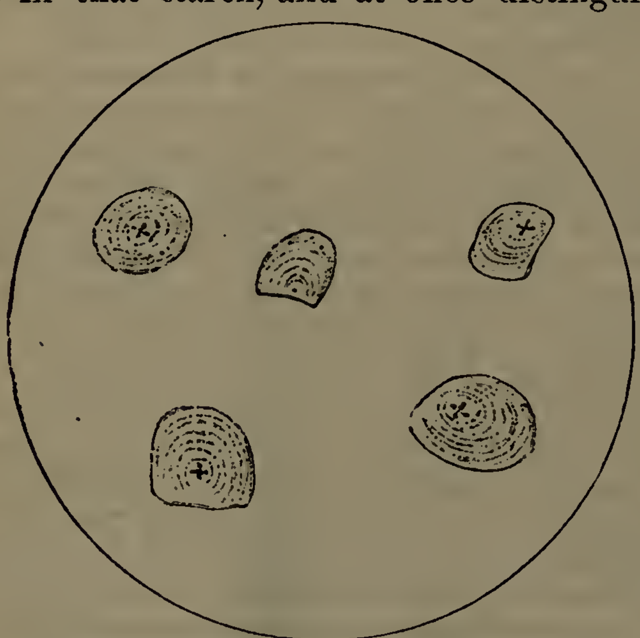

Fig. 2. Rio arrowroot (Manihot ?)

from starches of similar shape and size. Maize starch most closely resembles it, but is much more angular.

* Del. ad nat. E. J. P.

The longitudinal hilum of pea, bean, and lentil starches and their ovate shape are quite characteristic

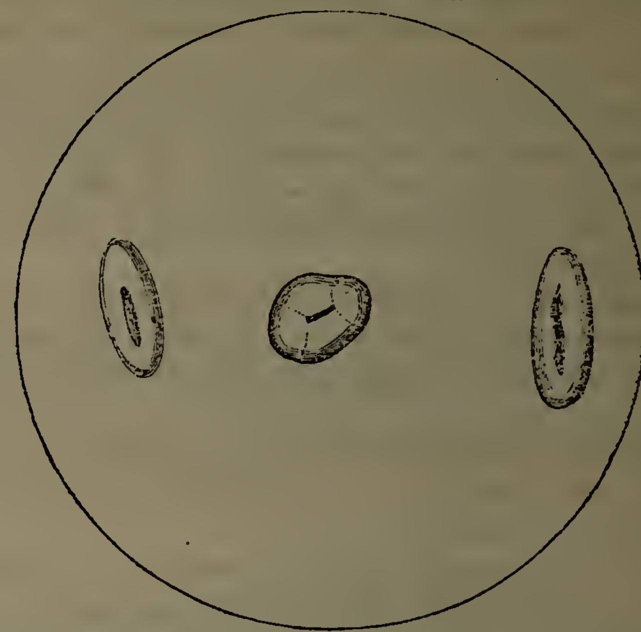

Fig. 3. Pea starch (characteristic of leguminous starches generally).

and do not require much care in their identification.

Potato starch, as pointed out by me in a paper read before the Pharmaceutical Conference at Bradford,

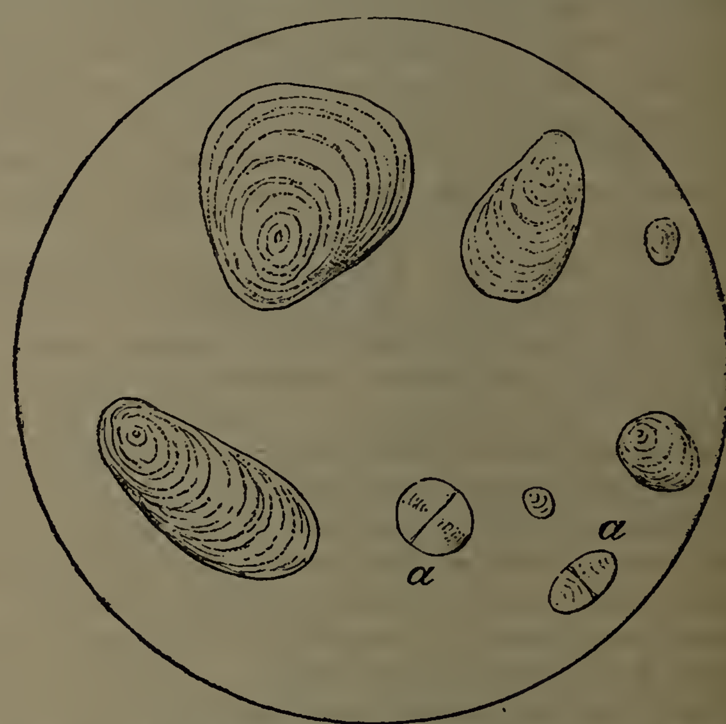

Fig. 4. Potato starch (abnormal forms shown at *a* are of frequent occurrence).

varies very much in size and shape, and is extremely difficult to identify unless present in large quantities.

Wheat starch is also very variable in size, but,

Fig 5. *aa*, Wheat starch. *b*, Altered granule. *cc*, Arrowroot used as an adulterant of pepper, ginger, etc.

when not changed by drying after being wetted, or by being heated, is very constant in shape, and assumes the form of flattened circular discs (which are capable of acting as lenses and forming a perfect image when immersed in a highly refracting medium, but other starches agree in this); when heated or dried the granules curl up, become twisted, and assumes various shapes of which the typical form is shown at *b* in fig. 5.

A cheap form of arrowroot is shown at *c* in fig. 5, and is evidently derived from a member of the ginger order. It has been largely used as an adulterant of pepper.

The small angular granules of rice starch are shown in fig. 6. The hilum is in the centre, but is not

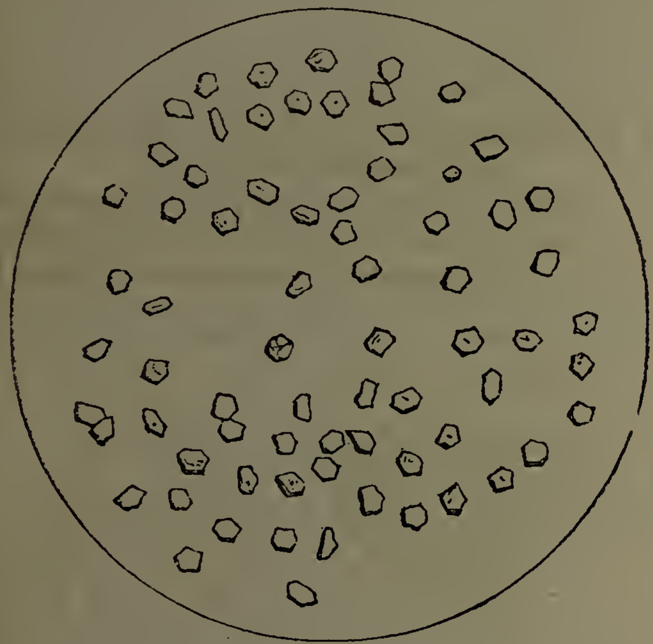

Fig. 6. Rice starch.

distinguishable without the use of a higher power than many microscopists possess.

The plan pursued in making a microscopical examination of ground ginger does not differ in any essential particular from that followed in the examination of pepper, and described in the article already referred to, but the exercise of greater care is demanded on account of the variety of shape and size of the ginger starch. It is very desirable that the analyst should make himself familiar with the structure of the rhizomes, and the examination of thin sections, and particularly with the cells containing the well-known greenish yellow colouring matter, and with such portion of the epidermal structure as may be adherent to inferior ginger. Sections may be very readily made by soaking a piece of the rhizome in water for a short time, and having fixed it in some form of section instrument,* slicing it with a good razor. Sections may be mounted in glycerine.

THE EXAMINATION OF BEER FOR ADULTERANTS.†

BY G. C. WITTSTEIN.

The author first refers to the addition of potash or soda to sour or stale beer. The presence of either can be determined by the proportion of ash yielded, which from Bavarian beer should not exceed one-half per cent. In a foot note the author observes that this percentage applies only to German beers, and especially Bavarian, since according to the experiments of T. Dickson,* English beers are much richer in ash. Simply testing the ash for the presence of potash or soda would be insufficient, since both the raw materials of beer—malt and hops—contain these alkalies. The author states that some experimenters have been betrayed into this error, and having found these alkalies have declared beer to be adulterated.

The author divides the other possible adulterants into two classes, "sweet" and "bitter." In the "sweet" class he mentions only glucose and glycerine.

The use of glucose would lead to an economy of malt, but of course it can only compensate for the malt sugar. As, however, in the course of fermentation through the formation of alcohol all or almost all the glucose would disappear, such beer would be abnormally poor in extractive. Glycerine not being capable of undergoing fermentation, Dr. Wittstein thinks that its addition does not allow of any reasonable explanation, and that the brewer who would add a sweet syrupy solution to his manufacture would prove himself to be wanting in prudence.

The substances included in the "bitter" class are—aloes, buck bean (menyanthin), gentian root (gentipicrin), colchicum root, flowers, and seeds (colchicine), colocynth (colocynthin), cocculus indicus (picrotoxin), nux vomica (brucine and strychnine), picric acid, quassia (quassiin), wormwood (absinthin). All of these substances are or contain bitter principles of so permeating and decided a nature, that smaller quantities of them than are usually used of hops impart great bitterness. They lack, however the aroma and other important ingredients in beer, such as resinous matter and tannin. Moreover, the majority of them possess poisonous properties.

As innocuous amongst these bitter substances may be reckoned buck bean, gentian, wormwood, and perhaps also quassia; more doubtful, because in small quantities violently purgative, are aloes and colocynth. The remaining four—colchicum, cocculus indicus, nux vomica, and picric acid—are decidedly dangerous, and especially the active principles of the first three—colchicine, picrotoxin, brucine and strychnine. Notwithstanding, therefore, that in the testing of beer generally the whole of the bitter substances mentioned should receive attention, the latter are the more important because of their peculiar virulence. But the author adds that up to the present time he has no knowledge of any one of them having been positively and with certainty referred to any beer; either because the beers actually examined did not contain them, or because in former years the detection of most of them was especially difficult. This difficulty, however, he considers has now been overcome through the progress made in organic chemistry.

The author does not appear to think that the use of these bitter substances in beer prevails to any great extent in Bavaria, and he considers that under ordinary conditions of price, hops are still the cheapest bitter for beer. He refers to the prevalent suspicion that cocculus indicus is added to beer by the brewer not only to increase its bitterness, but also to increase its stupefying power. He remarks that the notorious fact that a much larger quantity of cocculus indicus is imported than is used for medicinal purposes has led, as in this country, to the conclusion that the largest portion finds its way into the beer breweries. This inference, however, Dr. Wittstein considers to be a very hasty one, since the greater part is used in the extirpation of vermin and the stupefying of fish.

The author recommends the following process of testing for the above-mentioned bitter substances in beer as one that he has repeatedly proved:—

One litre of the suspected beer is evaporated by a moderate heat to the consistence of a thick syrup. This is poured into a tared glass cylinder—capable of con-

---

* A very simple, efficient, and cheap section instrument has been devised by Mr. Walter White, a pharmacist of Litcham, Norfolk, which is specially adapted for pharmaceutical work. A system of wedges advantageously replaces the usual screw in thi instrument.

† Abstract of paper in the *Archiv der Pharmacie* for January, 1875.

* *Philosophical Magazine* [3], vol. xxxiii, p. 341.

taining ten times its volume—and weighed; five times its weight of 93° to 95° alcohol is added, and the whole frequently stirred by means of a thick glass rod during twenty-four hours. By this means all the gum, dextrin, sulphates, phospates, and chlorides are separated, and a comparatively small portion is obtained in solution. After clearing, this solution is decanted, the residue is again treated with fresh alcohol, the two products mixed, filtered, and the alcohol driven off by a gentle heat.

(*a*) Of the syrupy residue left after this evaporation a small portion is diluted with three times its quantity of water; a strip of white woollen material is then allowed to lie in the solution during an hour, after which it is removed and washed repeatedly with pure water. If after this treatment the wool remains white the absence of picric acid is demonstrated; but if picric acid be present the wool will have acquired a yellow colour that cannot be removed by washing.

(*b*) The remaining largest portion of the syrup is agitated for some time with six times its weight of pure colourless benzol (boiling point 80° C); this is decanted off and the operation is repeated with fresh benzol, and the two liquors—the first of which has become yellow, the second having scarcely changed colour—are evaporated at a gentle heat. The pale yellow resinous residue thus obtained may possibly contain brucine, strychnine, colchicine, or colocynthin. To ascertain this, three portions of the resin are placed on a porcelain capsule, one is treated with nitric acid (sp. gr. 1·33 to 1·40), another with concentrated sulphuric acid, and the third, after a few morsels of red chromate of potash have been added, also with sulphuric acid. A red colour produced by the nitric acid indicates brucine with certainty, and a violet colour, colchicine. A red colour produced by sulphuric acid indicates colocynthin, and a purple violet produced by sulphuric acid and bichromate of potash reveals strychnine. Resin, in which one or other of these colorations is produced, possesses an extremely bitter taste; that in which the coloration does not take place is also bitter, but the bitterness recalls the well-known hop flavour.

(*c*) The syrup which has been treated with benzol is freed, by gently heating, from the small quantity of benzol remaining and agitated twice with pure colourless amylic alcohol (boiling point 132° C.). The first portion of the alcohol acquires a more or less wine or golden yellow colour. It would take up any picrotoxin or aloes if present, and thereby acquire a strongly bitter taste. If neither of these two substances be present, the amylic alcohol does not become bitter, because neither the hop bitter, nor the remaining four bitter principles—absinthin, gentipicrin, menyanthin, and quassiin—are soluble in it.

In order to distinguish picrotoxin from aloes a portion of the first obtained amylic alcohol solution is poured upon glass and allowed to evaporate spontaneously. If a fine white crystallization be formed picrotoxin is present; if not aloes is present, and can also be recognized by its peculiar saffron-like odour.

(*d*) The syrup which has been treated with benzol and amylic alcohol is freed by means of blotting paper from the small quantity of amylic alcohol adhering to it—evaporation by heat being impracticable in consequence of the high boiling point of the alcohol—and shaken with anhydrous ether. This takes up the hop bitter yet present and absinthin. After evaporation the latter is easily recognized through its wormwood like aroma; it also gives a reddish yellow solution with concentrated sulphuric acid which changes quickly to an indigo blue colour.

(*e*) After treating with ether the syrup has yet to be tested for gentipicrin, menyanthin and quassiin. As it is now free from the hop bitter, a decidedly bitter taste would point to one of these three substances. Any remaining ether is removed and the syrup is dissolved in water, and filtered; to one portion is added strong ammoniacal solution of silver, and it is then heated. If it remain clear quassiin would be present; if a silver mirror be formed it would originate either with gentipicrin or menyanthin. Another portion is evaporated to dryness on porcelain, and concentrated sulphuric acid added. If while cold no change of colour take place, but in heating it becomes carmine red, gentipicrin would be present; menyanthin would give a yellowish brown colour gradually changing to violet.

INDIAN MEDICINAL PLANTS.*

BY B. EVERS.

In the *Indian Medical Gazette* of February 1 and March 1, Surgeon B. Evers, civil surgeon at Seoni, has some interesting notes on certain Indian medicinal plants. He says:—My experiments with indigenous drugs were conducted chiefly with the view of finding some really useful and common antiperiodic; but other drugs attracted my attention, and so step by step I have been lured on, and now I find that a very extensive field of labour lies before all of us. For much that is contained in these papers I am indebted to the valuable works of Roxburgh, Ainslie, Lindley, Waring, Drury, and others; but at the same time I must here state that whatever confirmatory or additional information I have gained has been obtained by personal observation and experiment. I purpose to take the various medicinal plants I have to remark on, in the order in which they have been tried by me.

Michelia Champaca (Nat. Ord. Magnoliaceæ; Champa tree). I was induced to make trial of the bark of this tree as a febrifuge, from what Waring mentions. "Further trials with this bark," says he, "appear desirable." I tried a decoction of the bark in ten cases of ague, and from my own experience, I can safely state that it is invaluable as a tonic and febrifuge. Dr. H. Lolliot, of Mauritius, employed it successfully "in the treatment of the low intermittent fevers of that island." (For directions regarding its use, see Waring's 'Pharmacopœia of India,' p. 6.) The root-bark is said to be emmenagogue, but of this I have not yet had proof. "The flowers beaten up with oil are applied to fetid discharges from the nostrils." From information obtained through the Conservator of Forests, I learn that only one other member, viz., the *Michelia nilagirica*, of this family is to be found in those parts. This plant is found on the Pachmari hills near the Mahadeo cavern, but in all probability it was planted there. I have not been able to make many trials with this bark, as unfortunately it is not procurable in any considerable quantity in these parts. I leave it to others to test the value of the drug.

Carica Papaya (N.O. Papayaceæ; Pawpaw tree). The milky juice of the unripe fruit has long been known as one of the best vermifuges; and in the West Indies the seeds powdered are used for the same purpose. The seeds are said to possess emmenagogue properties also. Even the ripe fruit is said to act as an abortifacient, and pregnant women are therefore prohibited from eating it. The juice of the pulp (of the ripe fruit I imagine) removes, it is said, freckles caused by exposure to the sun. Browne, in his 'Natural History of Jamaica,' states "that water impregnated with the milky juice of this tree is thought to make all sorts of meat washed in it tender; but eight or ten minutes steeping, it is said, will make it so soft, that it will drop in pieces from the spit, or turn soon to rags in the boiling." Drury says that "this circumstance has been repeatedly confirmed, and, moreover, that old hogs and old poultry, which are fed upon the leaves and fruit, however tough the meat they afford might otherwise be, are thus rendered perfectly tender and good, if eaten as soon as killed, but that the flesh passes very soon into putridity, nay, the very vapour of the tree serves the purpose; hence, many people sus-

---

* Reprinted from the *London Medical Record* for April 28 1875.

pend the joints of meat, fowls, etc., in the upper part of the tree, in order to prepare them for the table." In Barbadoes, the farmers mix the milky juice with the drinking-water for their horses, for the purpose, as they express it, "to break down the blood; and this is a remarkable fact that the effects of this dissolving power in the fruit is not confined to muscular fibre, but acts on the circulating blood." In 1866, when I visited the island of Barbadoes, I found that the unripe fruit pickled was largely used as an article of diet. In this country it is not only eaten pickled, but also curried. I can assure my readers that the unripe fruit makes a very palatable *chijki* (vegetable curry). I have employed the milky juice of the unripe fruit in the treatment of splenic and hepatic enlargements, and with good results. I have treated sixty patients with this drug, and in thirty-nine instances a cure was effected; in eighteen cases the results were not reported; and in three cases (of enormously enlarged spleens) relief was afforded. The mode of administration is this:—About a teaspoonful of the juice is collected and mixed thoroughly with an equal quantity of sugar; this mass is divided into three boluses; one to be taken morning, noon, and evening. For children, a single drop of the juice, mixed with sugar, is sufficient. The pulp of the unripe fruit (the rind being removed) "mashed" up with hot water, might be applied as a poultice over the enlarged gland. On this external application, however, I do not place much reliance. No ill effects result from the internal application of the drug. Some of the patients treated complained of a feeling of heat in the stomach, nothing more. When symptoms of gastric or intestinal irritation occur, I have found it necessary to combine opium or hyoscyamus with the juice. The drug appears to me to act as a tonic and deobstruent. My plan for ascertaining that there has been an actual diminution in the size of the enlarged gland, was to mark off with the nitrate of silver the limits of the affected organ when the patient applied for treatment; and after about a fortnight or month, percuss and mark off again in the same way. In very bad cases I have seen a decrease of from half an inch to an inch in perpendicular dulness. Patients have told me again and again that they felt considerably lighter in the side; and that (*ab khana hazm hota*) their digestion was now good. I believe that the drug is most active in cases where the stages of ague-cake, *i,e.*, the genuine amyloid spleen, has not yet been attained—in fact, when the deposit in the gland is still albuminoid. It acts much more rapidly than the hydrochlorate of ammonia, the bromide of potassium, or the external application of the biniodide of mercury ointment. From twenty to twenty-five days is the longest time that a patient is generally kept under treatment. A nutritious and liberal diet is also an essential adjunct in these cases.

Acorus calamus (N. O. Aroideæ; Sweet-flag). Ainslie says that "it is a very favourite medicine of the Indian practitioners, and is reckoned so valuable in the indigestion, stomach-aches, and bowel affections of children, that there is a penalty incurred by any druggist who will not open his door in the middle of the night and sell it if demanded." A bath made of the infusion of the root "is regarded as an effectual remedy for epilepsy in children." "Shroder informs us that it possesses virtues in obstructions of the menses, spleen, and liver." The Egyptians regard it as a valuable aromatic and stomachic. The Turks prepare a confection of the root, and employ it "as a preventive against contagion." "European practitioners have considered the root as tonic and aromatic; and occasionally prescribe it in cases of intermittent fever and dyspepsia." Dr. A. T. Thomson recommends it as an antiperiodic; and Dr. Æ. Ross reports that it is an excellent stimulant and diaphoretic; he looks upon it "as most serviceable in atonic and choleraic diarrhœa." As an insecticide, particularly with reference to fleas, I have always found it very efficacious; but for this purpose, the root must be obtained fresh. Last year, the chief cause of mortality among the house patients of the Seoni Main Dispensary was dysentery; the gaol population also suffered very much from the same disease. The disease is most prevalent about the middle of the rainy season, that is, during the months of July and August. The disturbance probably of the water-supply, especially when this is derived from tanks and streams, and the dampness of the season are, in some measures I think, accountable for the appearance of the disease. In many of these cases, a malarial taint could be detected. Ipecacuanha does not, I regret to say, always succeed in these cases. There were no less than sixty-nine cases of dysentery treated in the Main Dispensary during the months of July and August. I found a decoction of the rhizome of the *Acorus calamus* very effectual in arresting the flux of blood, especially in the dysentery of children. The decoction is prepared thus:—Of the bruised rhizome, two ounces; coriander seed, one drachm; black pepper, half a drachm; water, one pint; boil down to twelve ounces, and set aside to cool. The dose for an adult is an ounce three times daily; for a child, one to three drachms, sweetened with sugar, two or three times a day. Astringent extracts or quinine might be added if necessary. The decoction is not only useful in dysentery and diarrhœa, but also in the bronchitic affections of children. I have often taken it myself when suffering from a bad cold in the chest. I think the drug is one well worthy of more extended trial.

Cochlospermum gossypium (N. O. Ternstrœmiaceæ). The pods contain a silk-cottony substance that might be used for stuffing pillows, etc. The bark has a faint aromatic odour, and yields on scarification a resinous exudation resembling myrrh. The natives use the branches of this tree for making torches. This plant is said, like the *Sterculia urens*, to yield a gum analogous to tragacanth. I have employed a decoction of the bark as a tonic and demulcent in cases of gonorrhœa. Of thirteen cases treated with the decoction, nine were decidedly cures, and in four the result was not known. The patients stated that after taking this medicine the scalding soon ceased. I found it necessary, however, to combine the sulphate or acetate of zinc in quarter-grain doses, to arrest altogether the discharge. The medicinal value of this plant is not, in my opinion, great.

Calosanthes Indica (N.O. Bignoniaceæ). The Gonds call this plant the "jaimangal;" and it was from a Gond that I first heard of its medicinal properties. The tree is common in Bengal, Burmah, South and Central India, Ceylon, and Java. According to Brandis, "the barks and fruit are used in tanning and dyeing, the seeds are used to line hats, and placed between two layers of wicker work to make umbrellas. Root, bark, leaves, and seeds are used in native medicine." The Gonds employ a decoction of the bark as a discutient application to rheumatic swellings. They do not, however, administer any part of the plant as an internal remedy. I have made trial of the powder and an infusion of the bark, and have found it to be most powerfully diaphoretic; the drug has slight anodyne properties; also a bath, prepared with the bark, I have frequently employed in rheumatism. Twenty-eight cases of acute rheumatism were treated with this drug, and in all the results have been most satisfactory. The dose of the powder is from 5 to 15 grains, three daily; of the infusion (1 ounce of bark to 10 ounces of boiling water) an ounce three times a day. Combined with opium, it forms a much more powerful sudorific than the compound powder of ipecacuanha. The drug does not possess any febrifuge properties. Roxburgh makes no mention of the medicinal qualities of this plant.

Pongamia glabra (N. O. Leguminosæ). The natives of the south of India thread the legumes and tie them round the necks of children suffering from whooping cough. It is said by them to be of use in these cases. Probably the friction of the legumes against the chest, or it may be, the exhalation from them, might have something to do in mitigating the distressing cough. I have employed the powder of the dried pericarps in the treatment of whooping cough (fourteen cases), and in chronic bronchitis (twenty-five cases), and must acknowledge its efficacy in these affections. Most of my patients were quite relieved in from ten to twelve days. For an adult the dose of the powder ranges from five to ten grains; for children, one to three grains, thrice daily, given with a little syrup or honey.

The oil obtained (by expression) from the seeds is employed by the natives in the treatment of "scabies, herpes, and other cutaneous diseases." It is also employed as an embrocation in rheumatic affections. According to Brandis, "the pods and the leaves are used in native medicine."

Holarrhena antidysenterica (N.O. Apocynaceæ. Seeds). —An infusion of "the oat-like seeds (Anderjun of the Taleef Shereef) is said to be effectual in arresting hæmorrhage from piles." "In the only two cases of this affection that came under my care I employed the drug with advantage. It is one well worthy of further trial. For further particulars regarding the value of this plant, I must refer my readers to Ainslie's 'Materia Medica,' vol. i., p. 88, and to Waring's 'Pharmacopœia of India,' p. 137. The bark (Conessibark) of this plant has long been held in high repute as a remedy for dysentery.

Jatropha Curcas (N.O. Euphorbiaceæ).—The juice of this plant is used by natives to arrest bleeding from wounds, etc. The seeds possess purgative properties; and the oil obtained from them is said to be useful in cutaneous affections and in chronic rheumatism. Not long since my attention was attracted to a notice of this plant in the *Indian Medical Gazette*, by Mr. Udoy Chund Dutt. He reports that the milky juice of this plant is a most powerful hæmostatic. In two cases, in which trials were made, he says that the bleeding was at once arrested; and to use his own words, '*the blood seemed to be at once curdled up.*' Before this notice appeared, I had the following case under treatment. Bugloo, aged twenty-five, was admitted into the Seoni Main Dispensary on October 3, 1874. He was suffering from a large open abscess in the heel of the right foot; the abscess had resulted from an injury. The patient stated that it was not so much the pain and swelling of the foot that caused him anxiety, but the frequent hæmorrhages from the abscess. On removing the rags, etc., that enveloped the foot, hæmorrhage (evidently venous) at once occurred. Immediately above the internal malleolus I found a pulsating tumour about the size of a pigeon's egg; pressure on the posterior tibial artery on the proximal side of the swelling at once arrested the bleeding; the superficial veins in the neighbourhood were enlarged, and a faint thrill could be detected in them. Taking into consideration the situation of the tumour, and the character of the hæmorrhage, I diagnosed the case as one of varicose aneurism. The bleeding from the tumour was easily checked by the application of the tourniquet, but the distress occasioned by the pressure of the instrument was so great, that before evening the patient begged that it might be taken off. After this, instrumental and digital pressure were resorted to alternately. In the meantime the abscess in the heel was gradually filling up. On seeing Mr. Udoy Chund Dutt's paper, I determined to give the jatropha juice a trial; and, accordingly, on October 12, I injected a drachm of the juice into the tumour by means of the hypodermic syringe. The result was astonishing; in twenty minutes time the pulsation was so faint that no non-professional person could have detected it; and by evening all pulsation had ceased, a good firm coagulum had been produced. The nozzle of the syringe was retained in the tumour for about ten minutes; and on removing the instrument just one drop of blood escaped through the puncture; a small piece of dry lint and a piece of sticking-plaster were applied to the puncture. No ill effects resulted from the injection of the juice. I was anxious to watch the result of this treatment further; but on the evening of October 16 the patient left the hospital without permission, considering that it was no longer necessary for him to stay in Seoni. People from his village inform me that the man is now (fully three months after the operation) quite well. This is only a single case it is true, but it illustrates how a very simple and speedy operation may be had recourse to in place of others more serious. We all know what a difficult thing it is to treat aneurismal affections. Holmes in his 'System of Surgery' (vol. iii., p. 512) has the following passage:—"The discovery of a fluid of great coagulating power, and devoid of irritating properties, is a desideratum in this method," *i.e.*, the treatment of aneurisms by injections.

I make no pretensions to originality, but I ask that others with better opportunities than myself may give this drug a trial. Two children were brought to me for the purpose of having the frænum of the tongue snipped, and in both these cases, after the operation, I employed jatropha juice as a styptic; there can be no doubt of the value assigned to it by natives. The *Jatropha Curcas* is a very common hedge-plant. Drury states that the juice "is of a very tenacious nature, and, if blown, forms large bubbles, probably owing to the presence of caoutchouc." "A decoction of the leaves is used in the Cape Verd Islands to excite secretion of milk in women."

Sesamum Indicum (N. O. Pedaliaceæ).—Not long ago I found in the *Pioneer* newspaper that the mucilage obtained from the leaves of this plant is considered a specific for dysentery in some parts of Australia, and this led me to make trial of the drug. Waring remarks on this subject:—"The leaves (sesami folia or Benne leaves) are officinal in the secondary list of the United States Pharmacopœia; they abound with thick viscid mucilage, which is readily imparted to water, and an infusion of them is much used in the the southern states of North America in all affections requiring demulcents. One or two full-sized fresh leaves, infused or agitated in half a pint of cold water, will soon render it sufficiently viscid for the purpose. If the dried leaves be used, hot water should be substituted for the cold. How far the leaves of the Indian-grown plant may be used in this way, remains to be determined." I have employed the mucilage, obtained from the leaves of the Indian plant, in the treatment of sixteen cases of dysentery, and in all recovery followed. From six to seven days was the time necessary for such treatment. I confess, however, that my cases were not of the virulent type seen towards the end of the rainy season. The drug acts simply as a demulcent, and does not, in my opinion, exert any specific influence on the disease; furthermore, it is necessary to combine an opiate with it, to relieve the tenesmus, so that probably the opium added has as much to do in checking the disease as the mucilage itself.

Waring again states that "the seeds have powerfully emmenagogue properties assigned to them, and it is believed by the natives and Indo-Britons that, if taken largely, they are capable of producing abortion. The alleged emmenagogue properties of these seeds deserve further investigation." In three cases of congestive dysmenorrhœa I administered the powder of the seeds in ten-grain doses, three or four times a day, with benefit. I have at the same time employed the hip-bath recommended by Waring. It is commonly believed in the south of India that the seeds, when eaten by a pregnant woman, are likely to induce abortion; but no instance of the kind has ever come under my notice, nor have I heard of any. Further trials with the drug are necessary. The seeds of this plant yield the common til or jingelly oil of commerce. The leaves of the *Pedalium murere*, another plant of the same natural order, also yield a viscid mucilage when agitated in cold water. The natives use the mucilage thus obtained as a demulcent and diuretic in the treatment of gonorrhœa, and there can be no doubt of its value in such cases. The plant is very common in the south of India.

NOTE ON DILUTED PHOSPHORIC ACID.*

BY H. H. CROFT.

Professor of Chemistry, University College, Toronto.

Some months since, a druggist of Yorkville called my attention to the fact that a white precipitate is formed on adding a solution of glacial phosphoric acid to ferric chloride (tincture of iron). Before I had leisure to make any experiments on the subject, a notice appeared in the *Canadian Pharmaceutical Journal* for April, of some investigation by Mr. L. Dohme, who arrived at the conclusion that the precipitate so formed was due to pyrophosphoric acid.

So-called glacial phosphoric acid, is, when properly prepared, metaphosphoric acid; HO PO_5, old formula; H PO_3, new empirical, $\left.\begin{matrix}PO\\H\end{matrix}\right\} O_2$ typical. When dissolved in cold water it remains unchanged, but when warmed gradually passes into pyrophosphoric acid, H_2O_2 PO_5; $H_4P_2O_7$; $\left.\begin{matrix}2\ PO\\H_4\end{matrix}\right\} O_5$, by absorption of water, and finally into common or tribasic acid, $H_3O_3PO_5$; H_3PO_4; $\left.\begin{matrix}PO\\H_3\end{matrix}\right\} O_3$, these acids being referable respectively to the types of $\left.\begin{matrix}H_2\\H_2\end{matrix}\right\} O_2$, $\left.\begin{matrix}H_5\\H_5\end{matrix}\right\} O_5$, $\left.\begin{matrix}H_3\\H_3\end{matrix}\right\} O_3$. The ordinary distinguishing tests employed are as follows, of course, for the free acids.

Tribasic phosphoric acid gives no precipitate with silver nitrate, barium chloride, or albumen.

Dibasic phosphoric acid gives a precipitate with silver nitrate and barium chloride, but none with albumen.

Monobasic phosphoric acid gives a precipitate with all three.

This latter acid is usually prepared by dissolving phosphorus in nitric acid, by long digestion, evaporating and heating so as to drive off as much water as possible; or by heating common ammonium phosphate

$$\left.\begin{matrix}PO\\(NH_4)_2H\end{matrix}\right\} O_3 - (NH_4)_2O = \left.\begin{matrix}PO\\H\end{matrix}\right\} O_2.$$

Prepared in either of these ways and dissolved in cold water, it gives an immediate whitish precipitate with ferric chloride, as also with albumen; both these precipitate even in moderately dilute solutions. Heated for some time, it loses its power of precipitating albumen, but continues to act upon ferric salt. Boiled for a long time it precipitates neither. Pyrophosphoric acid obtained by decomposition of the lead salt by hydrosulphuric acid, exhibits the same reaction as regards ferric chloride; boiled for some time it loses this power, being converted into tribasic acid.

It appears therefore that both pyrophosphoric acid (Dohme) and metaphosphoric acid possess the power of producing a precipitate in ferric chloride, I may add, insoluble in acetic acid and not very easily soluble in hydrochloric acid, and hence ferric chloride may be employed as a good test for distinguishing the phosphoric acids. I am not aware that this fact has been noticed, and we are indebted to Mr. Dohme for its discovery. The numerous experiments which have led to this paper were made for me by Mr. Cathron.

In using glacial phosphoric acid for medicinal purposes, it would therefore be well to boil the solution for some time, say half-an-hour, before adding to the solution of iron.

For convenience of students, I append formulas showing derivation of acids and salts.

$\left.\begin{matrix}PO\\H_3\end{matrix}\right\} O_3$ = Common or tribasic acid.

$\left.\begin{matrix}PO\\H_3\end{matrix}\right\} O_3 - H_2O = \left.\begin{matrix}PO\\H\end{matrix}\right\} O_2$ = Metaphosphoric or monobasic acid.

$\left.\begin{matrix}2\ PO\\H_6\end{matrix}\right\} O_6 - H_2O = \left.\begin{matrix}2\ PO\\H_4\end{matrix}\right\} O_5$ = Pyrophosphoric or tetrabasic acid.

$\left.\begin{matrix}PO\\Na_2H\end{matrix}\right\} O_3$—Common phosphate of soda.

$\left.\begin{matrix}2\ PO\\Na_2H\end{matrix}\right\} O_3 - H_2O = \left.\begin{matrix}2\ PO\\Na_4\end{matrix}\right\} O_5$ = Pyrophosphate of soda.

$\left.\begin{matrix}PO\\NaH_2\end{matrix}\right\} O_3 - H_2O = \left.\begin{matrix}PO\\Na\end{matrix}\right\} O_2$ = Metaphosphate of soda.

MONOBROMATED AND DIBROMATED CAMPHOR.*

BY J. DE MONTGOLFIER.

Monobromated Camphor.—The method of preparing this compound has already been described in this Journal.† The author gives the following information respecting its chemical and physical properties.

Monobromated camphor is slightly soluble in cold alcohol, very soluble in chloroform, perchloride of carbon, benzol, etc. Heated a little above its fusing point it sublimes in beautiful very slender needles, frequently several centimetres in length. It is dissolved by cold sulphuric acid and reprecipitated by water without alteration. Ordinary nitric acid has no action upon it in the cold, and when heated it does not attack it even after an ebullition of several minutes; but if the liquid be then allowed to cool it separates into two layers, one of which consists of a compound analogous to that of camphor and nitric acid. If the excess of acid be decanted the oily layer after a few days deposits the monobromated camphor in crystallized needles. Fuming nitric acid in the cold immediately forms a layer that floats on the surface. If monobromated camphor be carefully precipitated with water from its alcoholic solution it separates in slender needles several millimetres in length.

This body possesses the rotatory power; in alcoholic solution and for the ray D, the power is 139°. One of its most interesting properties is that nascent hydrogen regenerates from it the primitive camphor, the hydrogenation being rapid and easy by the action of a 2 per cent. sodium amalgam upon an alcoholic solution.

By slow crystallization, monobromated camphor is deposited from its solution in alcohol or chloroform only in very elongated and very deformed crystals. From boiling alcohol, however, it crystallizes in right prisms with a rhombic base.

Dibromated Camphor.—For the preparation of this body it has been directed to heat one equivalent of monobromated camphor with two of bromine. The author finds it more simple and rapid to heat in sealed tubes one equivalent of camphor and four of bromine. Even under considerable pressure and with thin tubes it is rarely that an explosion takes place, the product appearing to form an unstable compound with the hydrobromic acid. In whatever way it may be prepared the product is enclosed in a considerable quantity of liquid; sometimes the crystals are not deposited immediately, but if the liquor be left to itself it eventually crystallizes. The viscous liquid which remains contains less bromine than the dibromated camphor; it is a mixture and after a time becomes nearly solid. The yield of dibromated camphor is always very small.

This body does not sublime perceptibly at 100° C. It is less soluble in cold alcohol than the monobromated camphor, it is soluble in chloroform, perchloride of carbon, and benzol. It possesses nearly all the properties of monobromated camphor: sulphuric acid dissolves it without alteration, and ordinary and fuming nitric acid have the same action upon it as upon the latter. Dissolved in alcohol it is easily hydrogenated by sodium amalgam, the

* From the *Bulletin de la Société Chimique.*
† *Pharm. Journ.*, [3]., vol. v., p. 321.

primitive camphor being regenerated. Its rotatory power in alcoholic solution is 102° C. The rotatory power is therefore not sensibly modified in the passage of monobromated to dibromated camphor.

Boiling alcohol deposits this body under the form of an almost odourless crystalline powder; slow crystallization from alcohol or chloroform yields fine crystals which are right prisms with rhombic base.

The characteristic property of camphor to combine with acids and a great number of other bodies is persistent in its bromine derivatives. Thus the viscous matter obtained in the preparation of dibromated camphor is an unstable combination of that compound with hydrobromic acid, dissolved in a small quantity of carbide. This product is strongly acid, and if left to stand in a vessel slowly disengages hydrobromic acid, the dibromated camphor crystallizing at the same time. When all the hydrobromic acid is given off there remains but little of this liquid, and it proves upon analysis to contain less bromine than required by $C_{10}H_{14}Br_2O$. It is only a solution of dibromated camphor in a viscous carbide.

The action of nitric acid upon camphor is known, and the author has found that it comports itself in the presence of other acids absolutely in the same manner as its bromine derivatives. It dissolves in sulphuric and phosphoric acids. Shaken in a tube with very concentrated hydrochloric acid, it appears at first to dissolve and disappear; but it quickly separates as an oily layer on the surface as with nitric acid. Hydrobromic and hydriodic acids would probably give analogous results.

THE THERAPEUTIC ACTION OF OLEUM ALEURITIS TRILOBÆ.

BY DR. CALIXTO OXAMENDI.

In a paper published in the *Anales de Medicina de la Habana*, an abstract of which appears in the *Medical Record* for June 16, the author describes the therapeutic action of the oil of the Candleberry tree, which he considers may be used as a good substitute for castor-oil.

The *Aleuritis trilobæ*, commonly called in India "candlenut" or "candleberry" tree, is a large euphorbiaceous tree which grows in India and all intertropical countries. The oil produced from the nuts of this tree is used for different industrial purposes. The native of Ceylon calls it "kekune oil," and it is known in England under the names of "nut oil" or "artist's oil."

Very little has hitherto been said about the therapeutic properties of this plant; nothing can be found on the subject in the works treating of materia medica. A short notice is, however, given in Griffith's 'Medical Botany.' This author says:—"The nuts of the *Aleuritis triloba* are considered to be aphrodisiac when used in small quantity and in a dry state; they have laxative properties when taken in larger quantity and in a fresh state." In one of his 'Annuaires de Thérapeutique,' M. Bouchardat says that the oil of *Aleuritis triloba* has purgative properties in a dose of thirty grammes. Renato de Grosourdy expresses the same opinion in his work on medical botany, but he thinks the oil must be used in a dose of sixty grammes in order to move the bowels.

Following the indications of Bouchardat and Grosourdy, Dr. Oxamendi has employed the oil of *Aleuritis triloba*, and his results are not quite conformable with those arrived at by his predecessors. Having once given this medicine to a healthy negro woman, he obtained an effect much stronger than he expected. By subsequent experiments, he arrived at the conclusion that the oil must be employed in much smaller doses, and that half an ounce is quite sufficient to move the bowels of an adult.

The oil of *Aleuritis*, Dr. Oxamendi thinks, may be used with advantage as a substitute for other aperients. It greatly resembles castor-oil in its effects on the bowels, but it is by no means disagreeable, and has a pleasant taste of hazel nuts. It acts quickly (about three hours after its administration) and very gently, without giving pain and griping.

With respect to the physiological action of this aperient Dr. Oxamendi thinks the laxative effects are not only due to the disturbance produced in the bowels by the oil itself, but also to a special resin which irritates the intestinal mucous membrane.

The nuts of the *Aleuritis triloba* are so oleaginous that they yield nearly half their weight of oil. The dose of the oil is two drachms for a child or half an ounce for an adult. The following mixture is recommended by Dr. Oxamendi:—

℞. Olei nucis aleuritis trilobæ	℥ss
Gummi arabici	ʒiij
Aq. communis	℥iij
Sacchari albi	ʒss
M.	

Good results are also reported to have been obtained by making frictions with the following liniment over the abdomen in cases of rebellious constipation or abdominal pains:—

℞. Olei nucis aleuritis trilobæ	℥ss
Tinct. cantharid. } Ammon. carbon., aa	ʒiij
M. Linimentum.	

ANTAGONISM BETWEEN STRYCHNIA AND MONOBROMATED CAMPHOR.*

BY DR. VALENTI Y VIVO.

Dr. Valenti y Vivo has made a series of researches on the supposed antagonism between these two substances; and has arrived at the conclusion that monobromated of camphor may be considered as an antidote for strychnia. According to Dr. Valenti, the following conclusions are well established (*Siglo Medico*, April 18, 1875).

1. Twelve dogs, after taking a fatal dose of strychnia, were saved by the use of monobromated camphor. The experiments were practised in a satisfactory manner, with crucial tests.

2. The tetanic convulsions produced by strychnia may be reduced in force and frequence by the use of monobromated camphor. The action of the antidote is rapid and sure.

3. The hyposthenic action of the monobromated camphor mitigates the reflex activity of the poison. The tonic convulsions are converted into clonic.

4. The physiological antagonism is comparatively limited. A strong dose of monobromted camphor is necessary to antagonize the effects of strychnia.

5. The monobromated camphor acts on the sympathetic nerve; this is demonstrated by the myosis and the cardiac paralysis which were observed after its administration.

6. After an overdose of monobromated camphor, the united effects of the poison and the antidote produce death by syncope; when death takes place during the strychnism and without the antidote, cardiac impulses are observed *post mortem*; when it takes place after and through the use of bromide, cardiac impulses are never observed.

7. The experiments show that it is preferable to introduce the monobromated camphor by gastric ingestion, and in small and repeated doses. The subcutaneous method, employed in some experiments, has not given satisfactory results.

Dr. Valenti points out the importance of this antagonism in practical medicine. He thinks monobromated camphor may be used with advantage in cases of poisoning by strychnia, in quantity varying from four to six grammes, given in small doses.

The Pharmaceutical Journal.

SATURDAY, JUNE 26, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE IRISH PHARMACY BILL.

THE second reading of this Bill came on last Friday night, at a late hour, and it is with some satisfaction that we are able to state that our anticipations of last week were so far realized that Sir MICHAEL HICKS-BEACH, in proposing the second reading of the Bill, expressed himself as concurring with the objections that had been raised by the Pharmaceutical Society against the proposal that there should be entire reciprocity between the British and Irish Pharmaceutical Societies, as provided for in the 18th Clause of the Bill. In pursuance of this alteration in his views, the Chief Secretary for Ireland proposed to omit that portion of the Bill which refers to reciprocity between the British Society and the Society contemplated as being established in Ireland.

On Monday the House went into Committee *pro formâ* on the Bill, and on Monday next it will be brought before the House in its amended form.

We have on a previous occasion mentioned the opinion expressed by a medical journal, not altogether unconnected with Ireland, that the Government would pay no regard to the objections raised by the Pharmaceutical Society against the provisions of the Bill. An amusing illustration of the value attaching to the opinions thus expressed, is furnished by the announcement in the same journal this week, that Sir MICHAEL HICKS-BEACH would "stand by his measure in its integrity, even if Parliament must be kept sitting in the dog-days." As we have already stated the Chief Secretary for Ireland has formed a wiser estimate of the case. In speaking of the effect of the alteration he had adopted Sir MICHAEL admitted that, notwithstanding this omission of the provisions for reciprocity, the object which the Irish Bill has in view will be equally well met, and that so far as regards Ireland, the Bill will not be less effective without the 18th Clause than it would be if it were allowed to remain. We entirely agree with this opinion ourselves, and have no doubt that it will meet with general acquiescence.

So far then as the regulation of Pharmacy in Ireland is concerned, those who think this can be provided for better by the establishment of an independent Irish Society than by the extension of the British Society's operations to Ireland, in the same way that it already extends to Scotland, cannot have any reason to complain of the action taken by the Society in reference to the Bill. We are therefore utterly at a loss to comprehend the complaint of Mr. ERRINGTON—who may be assumed to represent the advocates of the Irish Society scheme—that the dropping out of the reciprocity clause was a mutilation of the Bill. We cannot understand why the provisions of the 18th Clause having that object in view should be so tenaciously held to by the supporter of a measure that is ostensibly intended to provide specially for the independent control of Irish pharmacy, nor can we understand why the withdrawal of this reciprocity clause should be regarded by them with so much regret as Mr. ERRINGTON took occasion to express last Friday. The reciprocity clause in fact did not in any way affect the internal regulation of pharmacy in Ireland, which is supposed by some to be so essential; it merely provided that persons having at some future time the certificates of a Society which is at present non-existent, should in virtue of those certificates have also the right to registration in Great Britain among the highest grade of pharmacists, and thereby acquire equal privileges with them. At the same time no provision was made for securing British pharmacists from such misuse of those powers as we know has been practised by certain qualifying medical bodies, with very prejudicial results not only to the profession and to the public, but also to the medical corporations themselves. It might reasonably have been expected that if reciprocity were so much desired together with independent action, the propriety of giving the British Society some control over the examinations would have been evident to the promoters of an independent Irish Pharmaceutical Society that was to enjoy the privilege of granting qualifications virtually extending to both countries.

It is from considerations such as these that it appeared at least expedient if not obligatory for the Society to oppose the Irish Pharmacy Bill. No communications had been made to the Council either by the Government or by the Irish promoters of the Bill, and though in the abstract there might not be objection to a reciprocity of privileges between Irish pharmacists and their brethren in England and Scotland, the proposition to establish such a relation was so put forward in the Bill that there was in reality no other course than opposition possible.

With the exception of the view expressed by Mr. ERRINGTON, who appears to entertain opinions in regard to pharmacy that are eminently peculiar, the only other objection to the withdrawal of the 18th Clause of the Bill was urged by Dr. WARD, and this was apparently founded on a misconception. Dr. WARD seems to have taken the 18th Clause as providing for one uniform system of examination in pharmacy, and to have regarded its omission as tending to increase the evil that has so long existed in the medical profession. He pointed out with much force that the unworthy competition between bodies empowered to grant medical qualifications had been carried so far, and in the struggle for existence the obtaining of examination fees had become so much more palpably essential for the continuance of some corporations than anything else, that a candidate rejected by one corporation had only to pack up his carpet bag and drive off to some other place, whence he would return in a few days a legally qualified medical practitioner.

That such a result as regards the practice of pharmacy in England might in some degree have followed the passing of the Irish Pharmacy Bill would not have been at all impossible, if the 18th Clause, with its reciprocity provisions, had remained; and as Dr. Ward's remarks on the Bill were directed against the favouring of such a contingency, we congratulate British pharmacists upon having in reality his support in this matter. The tendency of his argument was, in fact, very much in the same direction as the evidence given by Mr. Sandford before the Special Committee last session, when in referring to the example of the medical profession he pointed out that all practitioners in England, Ireland, and Scotland had been brought into one register, under one general medical council, with one pharmacopœia, thus ensuring greater uniformity. As a parallel case he held that in pharmacy, now the countries were so much more accessible than they used to be, it is important to have a similar system; that, in fact, reciprocity was much less desirable than union; while above all he insisted very justly, that if the establishment of a separate society and a separate board of examiners were insisted upon it would be essential to exercise great care in giving those who passed the examinations "titles which were not used by our Society in London."

This leads us to another and very important consideration as regards the Irish Pharmacy Bill, viz., the title which it proposes to introduce as the indication of having passed the examinations of the independent Pharmaceutical Society of Ireland. Why should that particular title be selected for this purpose which has been for years recognized as the exclusive right of those who voluntarily submit to an examination which has been conducted in such a manner as to ensure, for all who pass it, a very high measure of esteem among medical and scientific bodies? The want stated to exist in Ireland does not require the appropriation of this title, and in all probability that want would, so far as it exists in reality, be better considered by the adoption of the title "dispensing chemist" as the means by which the public might distinguish between the mere chemist and druggist and that "chemist" who was legally qualified to dispense physicians' prescriptions.

Moreover if we consider the very remarkable nature of the idea that seems to be entertained in Ireland of the functions of the "pharmaceutical chemist," as pointed out in our article last week, there is ample reason for alarm. So far as one may gather from the evidence of Dr. Leet and Mr. Collins—both of them connected with the practice of pharmacy, and active participators in schemes for the reform of Irish pharmacy, the "pharmaceutical chemist" is little better than a huckster, according to the Irish ideal. Hence a further very cogent reason suggests itself for objecting to share this designation with our Irish neighbours, at any rate for the present, and until such time as the arrangements for doing so can be carried out with due regard for the efforts by which a certain degree of respect has been acquired for this title, and without imperiling the maintenance of such credit as it has gained so far without any assistance from those who now desire to make use of it.

When the Irish Pharmaceutical Society shall have been in existence for some time and have demonstrated its capability of existing independently it may be well to entertain projects of co-operation and reciprocity. Whenever such a position is realized we have no doubt that the British Pharmaceutical Society will take part in such mutual arrangements as Mr. Errington referred to in his speech last Friday, and then we believe there will be more reason to anticipate that the results would be satisfactory to all parties.

We cannot leave this view of the subject without again suggesting that the appropriation of the title of pharmaceutical chemist should not be pressed by our friends in Ireland.

SERRONIA JABORANDI.

We learn from the new number of the *Zeitschrift d. allgemeinen österreichischen Apotheker-Vereines* that on the 25th of May, at a sitting of the Vienna Medical College, Professor Drasche described the results of numerous experiments on men and animals with "Serronia Jaborandi." Not only were an infusion and a tincture used, but also an alkaloid which the Professor claims to have been the first to prepare and to which he has given the name "Serronine." Of this alkaloid he reports a yield of about 1½ grains from a drachm of Serronia Jaborandi leaves. All of these preparations caused profuse sweating and excretion of saliva, and induced striking physiological symptoms generally similar to those which have been attributed to the use of the Jaborandi yielded by the genus *Pilocarpus*. But, although at present the materials for forming a judgment are very meagre, it would appear probable that what the Professor terms "Serronia Jaborandi," and which he states to have been imported from Brazil through France, is yielded by a Piperaceous plant; *Serronia Jaborandi*, Guill., being a synonym of *Piper Jaborandi*, Vell. We have seen specimens of the leaves that were imported into France, and although they present characters showing they have not been derived from *Piper Jaborandi*, they certainly have been yielded by an allied species. This similarity of name and all that is said concerning the source from which Professor Drasche obtained his supply would seem to indicate that he experimented with the leaves of a species of *Piper*. Whether, however, the alkaloid is identical with that referred to before (p. 789) under the name of Jaborandine, or whether another powerful medicinal agent has been placed at the service of medical men, can only be decided by the aid of fuller information.

A HINT FOR KEEPERS OF LEECHES.

A correspondent of the *Pharmaceutische Zeitung*, in a recent communication to that journal, makes a statement which will interest all who have been troubled by a high death-rate amongst their leeches. Being engaged in making some experiments with salicylic acid it occurred to him to try how far it could be tolerated by leeches. The first couple experimented upon fell victims to an overdose, but a third, being kept in water to which only a very small quantity of acid had been added, was lively and well at the end of a month, whilst the water did not become foul either in smell or taste. Two other leeches were then placed in 100 grams of water and four drops of an aqueous solution (1 in 300) of salicylic acid added. After remaining two months in the same water, the leeches were quite healthy and the water was fresh and clear. The next experiment was upon a hundred leeches, kept in about a litre of water. The conditions appear to have been rather unpromising; the water was already turbid, slimy, and ill-smelling, and at the bottom of the containing vessel three leeches lay dead. These were removed, thirty drops of the solution of salicylic acid added, and the vessel set aside. The next morning the foul smell of the water had entirely disappeared, and the leeches were quite lively. The water was then poured off, the vessel purified, and the leeches cleansed and placed in a litre of fresh water to which twenty drops of the salicylic acid solution had been added. Since then the leeches have been healthy, there have been no further deaths, and the water remains sweet and bright.

These experiments would appear to be worth repeating, and we should be glad to receive any fresh information upon the subject.

A MISTAKE AND ITS CONSEQUENCES.

In the month of May, according to the *Bulletin Commercial*, a prescription was presented to a certain French pharmacien ordering 2 gr. 40 cent. of carbonate of lithium to be divided into twelve packets. The pharmacien, not having any carbonate of lithium in stock, sent out for it to another pharmacien, who supplied him instead with 2 gr. 50 cent. of sulphate of atropia. The mistake was not noticed; but the powders were made up, and one of them was administered to a child, whose life was probably saved only by the violent vomiting it produced. Both pharmaciens have consequently been arraigned before the *tribunal correctionnel*, and after their characters as careful pharmacists had been allowed to have proper weight, one was fined 100 francs for making the mistake, and the other 50 francs for not detecting it. Our contemporary considerately represents the individuals concerned and the locality by initial letters.

CIVIL SERVICE SERVANTS AND CO-OPERATIVE STORES.

In the House of Commons on Monday last, Sir Thomas Chambers gave notice that, on the motion for going into Committee of Supply, he would call the attention of the House to the absence from the reports of the Civil Service Inquiry Commission of any investigation into the complaints made against the system of trading now carried on by the servants of the Crown under the guise of Co-operative Stores.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

(Session 1874—1875.)

Distribution of Prizes.

On Tuesday, 22nd June, the Council of the above Association met in the Botany class room, Free Church College, Mr. Kinninmont, Vice-President presiding in the absence of the President (Mr. Greig).

The following prizes were awarded:—

Practical Chemistry.

First Prize.—Mr. William Murdoch, 34, Virginia St.

Second Prize.—Mr. William Lawson, 140, Parliamentary Road.

Third Prize.—Mr. George B. Key, 113, Buchanan St.

Fourth Prize.—Mr. Thomas Dunlop, 270, Govan Road, Goran.

Teacher, W. Dittmar, Esq., Professor of Chemistry, Anderson's University.

Tutorial Class.

First Prize.—Mr. J. J. Cunningham, 34, Rutherglen Road.

Second Prize.—Mr. Hugh Campbell, 133, Waterloo Street.

Third Prize.—Mr. John McCallum, 2, Armadale St., Dennistown.

Fourth Prize.—Mr. Thomas Fullarton, 34, Rutherglen Road.

Teacher, Mr. R. C. Lindsay, B.Sc.

Botany Class.

First Prize.—Mr. David Curle, 15, Willowbank Street.

Second Prize.—Mr. George B. Key, 113, Buchanan Street.

Third Prize.—Mr. Andrew Young, 15, Bellfield Street.

Fourth Prize.—Mr. Thomas Dunlop, 270, Govan Road, Govan.

Teacher, Mr. William Keddie, Teacher of Science, Free Church College.

Twenty members were enrolled for the Practical Pharmaceutical Chemistry Class. Nine presented themselves for examination.

Thirty-seven members were enrolled for Tutorial Class, twenty presenting themselves for examination.

Twenty-one enrolled for Botany Class, and seven came forward for examination.

The teachers all spoke highly of the progress made by the classes generally, several of the more advanced students having already passed their respective pharmaceutical examinations.

The customary vote of thanks to teachers, donors of prizes (Messrs. Greig, Currie, and Rait), to the Secretary (Mr. Fairlie), who had provided an abundant supply of fresh plants for the use of the Botany Class each night, and to the Chairman (Mr. Kinninmont) for presiding closed the proceedings.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, June 17. Professor Abel, F.R.S., in the chair. After the usual business of the Society, seven papers were read, the first of which, "Notes on the Chemistry of Tartaric and Citric Acid," by R. Warington, gave many important particulars connected with the manufacture of these acids, and also detailed accounts of the methods of analysis—many of them novel—of the various raw materials from which they are made. After this the Secretary read a communication "On the Action of Nitric Acid on Copper, Mercury, etc., especially in the presence of Metallic Nitrates," by Mr. J. J. Ackworth. Dr. Gladstone then gave a short account of the "Decomposition of Water by the Joint Action of Aluminium and Aluminium Iodide, Bromide, and Chloride, including instances of Reverse Action," by himself and Mr. Tribe. The other papers were "On Nitrosyl Bromide, and on Sulphur Bromide," by Mr. M. M. P. Muir; "On Achrematite, a new Molybdic Arseniate of Lead from Mexico," and "On certain New Reactions of Tungsten," both by Professor J. W. Mallet; and "On the Action of Chlorine on Acetamide," by Dr. Prevost. The meeting, which was the last of the session, was then adjourned until November next.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture VI.

Physical deterioration from Alcohol, continued. Influence on the vital organs. Mental phenomena induced by its use. Summary.

(*Concluded from page* 1021.)

Other Organic Changes.

In the eyeball certain colloidal changes take place from the influence of alcohol, the extent of which have as yet been hardly thought of, certainly not in any degree studied, as in future they will be. We have learned of late years that the crystalline lens, the great refracting medium of the eyeball, may, like other colloids, be rendered dense and opaque by processes which disturb the relationship of the colloidal substance and its water. By this means even the lens of the living eye can be rendered opaque, and the disease called cataract can be artificially produced. Sugar and many salts in excess, in the blood, will lead to this perversion of structure, and after long time alcohol acting in the manner of salt is capable, in excess, of causing the same modification. In the eyeball, moreover, alcohol injures the delicate nervous expanse upon which the image of all objects we looked at is first impressed. It interferes with the vascular supply of this surface, and it leads to changes of structure which are indirectly destructive to the perfect sense of sight.

In yet another mode alcohol perverts the animal mechanism. By some as yet obscurely definable interference with the natural transmutation of the colloidal substances into saline or crystalloidal, it gives rise to the production of an excess of some salines which appear in the fluid renal secretion. These saline matters accumulated in the blood from inability of the excreting organs to dispose of them, are directly injurious, and exist as possible causes for the promotion of cataractous changes in the crystalline lens, and varied changes in other of the colloidal tissues and membranes. They are also a cause of a disease local in character and produced by the very aggregation of saline products, particle by particle, into a compact mass like a stone. I refer to what is called *calculus*. In writing the history of one of the districts of England in which this disease is very prevalent, I expressed many years ago the view that alcoholic indulgence was one of the most telling agencies in the production of the malady. I have seen nothing since that would lead me to alter that statement.

Organic Nervous Lesions from Alcohol.

Lastly, the brain and spinal cord, and all the nervous matter become, under the influence of alcohol, subject, like other parts, to organic deterioration. The membranes enveloping the nervous substance undergo thickening; the blood vessels are subjected to change of structure, by which their resistance and resiliency is impaired; and the true nervous matter is sometimes modified by softening or shrinking of its texture, by degeneration of its cellular structure, or by interposition of fatty particles.

These deteriorations of celebral and spinal matter give rise to a series of derangements, which show themselves in the worst forms of nervous disease—epilepsy; paralysis, local or general; insanity.

But not a single serious nervous lesion from alcohol appears without its warning. As a man who, when drinking at the table, is warned that the wine is beginning to take decisive effect on his power of expression and motion, by certain unmistakable indications, so the slow alcoholic is duly apprised that he is in danger of a more permanent derangement. He is occasionally conscious of a failing power of speech; in writing or speaking he loses common words. He is aware that after fatigue his limbs are unnaturally weary and heavy, and he is specially conscious that a sudden fall of temperature lowers too readily his vital energies. The worst sign of impending nervous change is muscular instability, irrespective of the will; that is to say, an involuntary muscular movement whenever the will is off guard. This is occasionally evidenced by sudden muscular starts which pass almost like electrical shocks through the whole of the body; but it is more frequently and determinately shown in persistent muscular movements and starts at the time of going to sleep. The volition then is resigned to the overpowering slumber, and properly all muscular movement, except the movement of the heart and of the breathing, should rest with the will. But now this beautiful order is disturbed. In the motor centres of the nervous organization the foreign agent is creating disturbance of function. The fact is communicated to the muscles by the nervous fibres, and the active involuntary start of the lower limbs rouses the sleeper in alarm. Ignorant of the import of these messages of danger, the habituated alcoholic continues too frequently his way, until he finds the agitated limbs unsteady, wanting in power of co-ordinated movement—paralysed.

Deeply interesting as these phenomena from alcohol are, I must leave them here, omitting many others equally significant and equally plain, when they are once pointed out, even to the unprofessional mind. Let it be understood that in each description I have recorded only what alcohol can physically do to the animal economy. It is not always the cause of all or any of these phenomena. They may be induced by other influences and other agents, but it is an agency capable of effecting them, and it is actively employed in the work.

On some of the Mental Phenomena Induced by Alcohol.

The purely physical action of alcohol has been so far treated upon in the preceding pages. To that must now be added a few sentences on the influence this agent exerts over the mental functions. Of course such influence is actually manifested by and through physical means, but as yet these are not sufficiently clear to enable us to trace out the mental aberration through the physical process that has led to it. It is better therefore and simpler to treat the present subject in the mere abstract, passing from the agent to its results, without reference to the intermediate line of connection between cause and effect. These mental phenomena, in the chronic phase, correspond

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts.*

to the phenomena which belong to the second and third stages of acute alcoholic intoxication.

Loss of Memory or Speech.

One of the first effects of alcohol upon the nervous system in the way of alienation from the natural mental state, is shown in loss of memory. This extends even to forgetfulness of the commonest of things; to names of familiar persons, to dates, to duties of daily life. Strangely too, this failure, like that which indicates, in the aged, the era of second childishness and mere oblivion, does not extend to the things of the past, but is confined to events that are passing. On old memories the mind retains its power; on new ones it requires constant prompting and sustainment.

If this failure of mental power progress, it is followed usually with loss of volitional power. The muscles remain ready to act, but the mind is incapable of stirring them into action. The speech fails at first, not because the mechanism of speech is deficient, but because the cerebral power is insufficient to call it forth to action. The man is reduced to the condition of the dumb animal. Aristotle says, grandly, animals have a voice; man speaks. In this case the voice remains, the speech is lost; the man sinks to the lower sphere of the living creation, over which he was bo n to ri l .

The failure of speech indicates the descent still deeper to that condition of general paralysis in which all the higher facilities of mind and will are powerless, and in which nothing remains to show the continuance of life except the parts that remain under the dominion of the chain of organic or vegetable nervous matter. Our asylums for the insane are charged with these helpless specimens of humanity. The membranes of the nervous centres of thought and volition have lost, in these, the dialysing function. In some instances, though less frequently than might be supposed, the nervous matter itself is modified visibly in texture. The result is the complete wreck of nervous action, the utter helplessness of will, the absolute dependence upon other hands for the very food that has to be borne to the mouth. The picture is one of breathing death; of final and perpetual dead drunkenness.

Dipsomania.

A second effect of alcohol on the mental organization, is the prodution of that craving for its incessant supply to which we give the name of dipsomania. In those who are affected with this form of alcoholic disease, a mixed madness and sanity is established, in which the cunning of the mind alone lives actively, with the vices that ally themselves to it. The arrest of nervous function is partial, and does not extend to the motor centres so determinately as to those of the higher reasoning faculties. But the end, though it may be slow, is certain. And the end is, as a rule, that general paralysis, which I have just described. The dipsomaniac is, however, capable of recovery, within certain limits, on one and only one condition—that the cause of his disease be totally withheld.

Mania a Potu.

The effect of alcohol on the mental functions is shown in yet another picture of modern humanity writhing under its use. I mean in the form of what may be called intermittent indulgence, to dangerous excess. This form of disease has been named the *mania a potu*, and it is one of the most desperate of the alcoholic evils. The victims of this class are not habitual drunkards or topers, but at sudden intervals they madden themselves with the spirit. They repent, reform, get a new lease of life, relapse. In intervals of repentance they are worn with remorse and regret; in the intervals of madness they are the terrible members of the community. In their final excitement they spread around their circle the darkness of desolation, fear, and despair. Their very footsteps carry dread to those who, most helpless and innocent, are under their fearful control. They strike their dearest friends; they strike themselves. Retaining sufficient nervous power to wield their limbs, yet not sufficient to guide their reason, they become the dangerous members of our community, whom our legislators, fearing to touch the cause of their malady, would fain try to cure by scourge and chain.

To us physiologists these "maniacs a potu" are men under the experiment of alcohol, with certain of their brain centres (which I could fairly define to you if the occasion were befitting) paralysed, and with a broken balance, therefore, of brain power, which we, with infinite labour and much exactitude, have learned to understand. Our remedy for such aberration of nervous function, if we were legislators, would be simple enough; we should not whip the maniac back again to the potu; we should try to break up the term by taking the potu from the maniac. But then we are only physiologists. We have nothing to do with that 117,000,000*l*. of invested capital, and we are not practical in reference to it.

Transmitted Disease.

The solemnest fact of all bearing upon these mental aberrations produced by alcohol, and upon the physical not less than the mental, is, that the mischief inflicted on man by his own act and deed cannot fail to be transferred to those who descend from him, and who are thus irresponsibly afflicted. Amongst the many inscrutable designs of nature none is more manifest than this, that physical vice, like physical feature and physical virtue, descends in line. It is, I say, a solemn reflection for every man and every woman, that whatever we do to ourselves so as to modify our own physical conformation and mental type, for good or for evil, is passed on to generations that have yet to be.

Not one of the transmitted wrongs, physical or mental, is more certainly passed on to those yet unborn than the wrongs which are inflicted by alcohol. We, therefore, who live to reform the present age in this respect, are stretching forth our powers to the next; to purify it, to beautify it, and to lead it towards that millennial happiness and blessedness, which, in the fulness of time, shall visit even the earth, making it, under an increasing light of knowledge, a garden of human delight, a Paradise regained.

Summary.

In summary of what has passed, I may be briefness itself.

This chemical substance, alcohol, an artificial product devised by man for his purposes, and in many things that lie outside his organism a useful substance, is neither a food nor a drink suitable for his natural demands. Its application as an agent that shall enter the living organization is properly limited by the learning and skill possessed by the physician, a learning that itself admits of being recast and revised in many important details, and perhaps in principles.

If this agent do really for the moment cheer the weary, and impart a flush of transient pleasure to the unwearied who crave for mirth, its influence (doubtful even in these modest and moderate degrees) is an infinitesimal advantage, by the side of an infinity of evil for which there is no compensation, and no human cure.

ROYAL INSTITUTION OF GREAT BRITAIN.

The Action of Heat on Coloured Liquids.*

BY WALTER NOEL HARTLEY, F.C.S.

Demonstrator of Chemistry, King's College, London.

All substances whatever may be divided into two classes, the coloured and the colourless. By simple inspection it is impossible to distinguish one colourless liquid from another, but the case is very different with coloured substances. In dealing with compound substances derived from the metals, we find generally that a certain colour is characteristic of a certain metal. Thus

* Lecture delivered at the Royal Institution of Great Britain, Friday, April 30, 1875.

a blue is the tint which prevails in most compounds containing copper, while green is characteristic of nickel, and pink or red of cobalt. If we examine the colour of a metallic solution by transmitting light through it, and analysing this light with a prism, as Dr. Gladstone did in the year 1857,* we then get a spectrum which serves in some degree to identify the metal present in the solution. Taking, for example, three liquids containing the same metal—a green, a purple, and a red solution—the green chloride, the purple sulphate, and the red oxalate of chromium, we have such a diversity of behaviour with chemical reagents, and such a variety of tints, that it is not an easy matter to recognize the presence of the same base unless the light transmitted by those solutions is analysed by the prism, and if this be done in a wedge-shaped cell, we have the advantage of seeing through many different thicknesses of liquid at one glance. We then get a spectrum in each case with chromium compounds, which has a great similarity, its chief characteristic being that the red, green, and blue rays are transmitted, while all the yellow are cut out. It has long been known that certain metallic solutions darken on exposure to heat, and in this way prisoners sometimes effect a secret correspondence outside the prison walls. The method consists in writing with an invisible solution between the lines of their letters, which is afterwards developed by those who are in the secret. Such solutions have been called sympathetic inks, and one in particular, called Hellot's sympathetic ink, is the chloride of cobalt, which being of a pale pink colour, in the state of a dilute solution, on drying and heating turns a very dark blue. Writing executed with this ink is all but invisible until a hot iron be passed over it, when it appears beautifully distinct, and on cooling disappears again. The Fenian criminal, Barrett, when confined in the House of Detention, was found to have in his possession a small tube containing chloride of gold: in the woollen stockings sent to him was noticed some white powder, which could be shaken out. This was evidently for the purpose of secret correspondence. The powder was found to be sulphate of iron; writing with a dilute solution of chloride of gold would be invisible until washed over with sulphate of iron, which solution develops the characters. The blue colour of cobalt chloride (Hellot's ink) is more easily produced if the salt be mixed with calcium chloride; such a mixture is that used for the little instrument called the chameleon barometer. This, which is in reality a hygrometer, or an indicator of the amount of moisture in the air, consists simply of a piece of paper soaked in the two solutions, protected by a glass and frame. The way in which it is differently affected by dry and moist air may be easily seen. Placing two of these under different bell-jars, one containing a little vessel of oil of vitriol, which dries the air, the other a little water, which of course keeps it moist, the paper in the former will be blue, and that in the latter red; then, if their places be changed their colours change. That a solution of cobalt chloride could be turned blue by the addition of hydrochloric acid, of sulphuric acid, of alcohol, or of chloride of calcium, has for some time been known; it has also been noticed that an acid solution of chloride of cobalt, red at an ordinary temperature, becomes blue if heated, such being also the case with a dilute solution containing alcohol; furthermore, that a dilute solution, if heated under pressure in sealed tubes to a higher temperature than that of boiling water, becomes blue.

In 1871 I found that a strong perfectly neutral aqueous solution of the purest cobalt chloride, which had been prepared from Claudet's salt, changed colour with the greatest possible ease upon heating. A small tube-full held in the hand changed from deep crimson to a decided purple tint in a few minutes; a little of the solution smeared over the fingers soon became blue; and a quantity of the liquid heated in an open dish became blue at 70° C. It was noticed that a very small tube of flattened glass, containing a solution of cobalt chloride, which was perfectly transparent when cold, upon heating to 70° C. became quite opaque. It was evident that the change from red to blue noticed was not simply a difference in refrangibility of the transmitted light, but an increase in the quantity of light absorbed by the solution. Hence it appeared to be a matter of great interest to examine the change of colour by means of the spectroscope, and even to go beyond this, and examine the action of heat on all coloured liquids by the same means, but especially was it expected that the bromide and iodide of cobalt would yield intensified effects of the same kind. Observations have been made on about sixty different solutions, most of which were prepared from metallic salts. Many of these compounds had been but imperfectly examined, while others were quite new. The solutions were generally made by allowing cold water to stand for some days with the crystallized salt, giving it frequent agitation.

The examinations were made in wedge cells cut out of blocks of glass, and polished; one side of the cell was made by fixing on a piece of plate-glass by means of a screw clump. Two sizes of these hollow wedges were used to facilitate the examination of liquids of different intensities of colour. They were each of the same height, namely, three-quarters of an inch, the larger cells being at their thickest part three-quarters of an inch, diminishing to nothing; the smaller being not more than three-sixteenths of an inch thick. The refraction caused by the thick wedge of liquid was corrected by the wedge of glass which formed one side of the cell. A little copper hot-air cupboard, with two opposite sides of easily removable plates of glass, was used for heating the wedges filled with liquid. These wedges were covered with plates of glass, as far as possible to prevent evaporation. Sunlight was used when possible, and in many cases when this was impossible an argand gas burner was used, of such a construction that oxygen gas could be blown into the flame to increase the brilliancy and whiteness of the light.

The spectra of metallic solutions were noticed as being principally of three kinds: those caused by the uninterrupted transmission of certain rays, such as the blue by salts of copper and the green by nickel; those consisting of continuous spectra interrupted by sharp black bands, such as didymium and uranium salts yield; and those resulting from two groups of rays of different refrangibilities as the green and red seen in chromium salts, and the blue and red in cobalt compounds. Such spectra are those of dichroic solutions. The difference between monochroic and dichroic solutions is easily shown in the following manner, thus: when the spectrum of the electric lamp is thrown on to the screen, and a cell containing sulphate of copper or nickel is interposed, a simple green band of light appears; if, instead of a spectroscope slit, a round disc is used, only one image of this is seen; and if the image of the carbon points of the electric lamp be thrown on to the screen, when a prism is interposed containing nickel solution, one image, and that a green one, is formed. Taking a dichroic liquid such as chrome alum, we get a spectrum consisting of red and green rays, separated by a band of darkness; a disk of light becomes resolved into two, one of a rich red and the other of a green tint, both colours of great beauty; where the two disks overlap the original colour of the liquid is formed.

If we project the image of the carbon points through a hollow prism of the liquid, two images are formed, one red, the other green. Precisely the same thing occurs with cobalt chloride, but the two colours are purple and orange.

The amount of absorption of light taking place in different thicknesses of a solution is easily observed when wedge cells are used, and it is thus easy to ascertain what change will take place on diluting the liquid, provided water is without chemical action. Liquids presenting a

* 'Proceedings of the Royal Institution,' vol. ii., p. 336.

wedge-shaped spectrum alter in colour on dilution, in the ratio indicated by the relation of the angle of the wedge-shaped spectrum to that of the wedge cell. These solutions, having spectra bounded by perpendicular straight lines, are only slightly affected by dilution. Some crystallized chromate of potash was dissolved in as little water as possible, forming a beautiful canary yellow colour. This, when diluted to 12,000 times the original weight of the salt, was not greatly altered, the change being not in depth of tint but in brilliancy. Permanganate of potash shows five black lines in the green portion of the spectrum when much diluted with water, and three of these are perfectly well seen when looking through half an inch of liquid which contains only one part of the salt in 118,000 parts of water. The loss of colour caused by the dilution of ammonio-chloride of palladium is indicated by its wedge-shaped spectrum, and was illustrated by dissolving one grain weight of the salt in water and diluting the dark brown liquid till the colour disappears; a pint and a half of water was sufficient for the purpose. On repeating the experiment with permanganate of potash the liquid remained of a beautiful pink colour, even after five gallons of water had been added.

It is a remarkable fact, that although the first step in practical chemistry is the solution of a substance in water, it has hitherto not been ascertained what really takes place when this operation is performed, consequently we are in ignorance of the chemical constitution of the resulting liquid. The chief reason for undertaking this investigation was the hope that this question, to which very doubtful and unsatisfactory answers could alone be given, might be finally decided, and the work recorded has been well bestowed on the subject.

Most metallic salts form combinations with water; the ordinary carbonate of soda (washing soda) is the carbonate of the metal united with ten molecules of water, which may be separated in the form of steam by heating to 100° C. It therefore contains not far from two-thirds of its weight of water, and many other salts combine with water in the same way. Carbonate of soda, however, is colourless; but many *coloured* substances combine with different proportions of water to form compounds varying in colour; thus we see in the accompanying tabular statement the variation between the colour of the anhydrous salts and their different combinations with water are very striking. Many compounds do not lose all their combined water at 100° C., and these salts are amongst the number.

Substances Varying in Colour with their State of Hydration.

Anhydrous.	Compounds produced at 100° C. from ordinary Crystals.	Ordinary Crystals.	Colour of Solution. Strong.	Colour of Solution. Dilute.
$CuCl_2$ Yellow..	$CuCl_2 \cdot H_2O$	$CuCl_2 \cdot 2H_2O$ Blue	Grass green ..	Blue.
$CuBr_2$ Black and lustrous	$CuBr_2 \cdot H_2O$ Dark brown	$CuBr_2 \cdot 5H_2O$ Golden green ..	Red brown ..	Blue.
$CoCl_2$ Lavender; blue when hot	$CoCl_2 \cdot 2H_2O$ Purple; blue when hot	$CoCl_2 \cdot 6H_2O$ Cherry red	Deep red	Pink.
$CoBr_2$ Vivid green	$CoBr_2 \cdot 2H_2O$ Purple; blue when hot	$CoBr_2 \cdot 6H_2O$ Deep crimson ..	Deep crimson ..	Pink.
CoI_2 Lustrous intense black ..	$CoI_2 \cdot 2H_2O$ Moss-green	$CoI_2 \cdot 6H_2O$ Dusky red-brown .	Dark brown ..	Pink.
$NiBr_2$ Yellow..	($NiBr_2 \cdot H_2O$?) Dark red	$NiBr_2 \cdot 3H_2O$ Green	Madder brown..	Apple green.
NiI_2 Lustrous intense black ..	($NiI_2 \cdot 2H_2O$?) Dark brown	$NiI_2 \cdot 6H_2O$ Bluish green.. ..	Yellowish brown.	Apple green.

It is a remarkable fact the above-named substances are those which change colour most notably on heating their solutions, hence a number of conclusions have been arrived at as to the internal or molecular structure of these solutions. The spectroscope itself would be quite unavailable in giving us the desired information; but chemical research, aided by the observation of optical properties, yields what neither alone could do.

A distinct statement regarding this action of heat here follows:—

The Effect of Heat on Absorption Spectra.

When saturated solutions of coloured salts are heated to 100° C.—1st, there are few cases in which no change is noticed. 2nd, generally the amount of light transmitted is diminished to a small extent by some of the more refrangible, the less refrangible, or both kinds of rays being obstructed. 3rd, there is frequently a complete difference in the nature of the transmitted light. Anhydrous salts not decomposed, hydrated compounds not dehydrated at 100° C., and salts which do not change colour on dehydration, give little or no alteration in their spectra when heated.

Solutions of hydrated salts, and most notably those of haloid compounds, do change; and the alteration is, if not identical with, similar to that produced by dehydration and the action of dehydrating liquids, such as alcohol, acids, and glycerine, on the salts in crystals or solution.

A particularly interesting instance of the action of heat on an aqueous solution is that of cobalt chloride, which gives a different series of dark bands in the red part of the spectrum at different temperatures, ranging between 23° C. and 73° C. Band after band of shadow intercepts the red rays as the temperature rises, till finally nothing but the blue are transmitted. Drawings of six different spectra of this remarkable nature have been made. The changes are most marked between 33° and 53°, when the temperature may be told almost to a degree by noting the appearance of the spectrum. Though to the unaided eye cobalt bromide appears to undergo the same change, yet, as seen with the spectroscope, it is not of so curious a character, the bands being not so numerous.

With cobalt iodide a band of red and green rays is transmitted at low temperatures; the band of light moves towards the opposite end of the spectrum, with rise of temperature, until it is transferred to such a position that it consists of green rays only. In this instance the change to the eye is more striking when seen without the spectroscope, because the mixtures of red, yellow, and green rays, which are formed during the transition, give rise to very beautiful shades of brown and olive green. Thus a saturated solution at 16° C. was of a brown colour, at − 10° C. it became of a fiery red and crystals separated, at + 10° reddish brown, at 20° the same, at 35° vandyke brown, at 45° a cold brown tint with a tinge of yellowish green, at 55° a decidedly yellowish green in thin layers and yellow brown in thick, at 65° greenish brown, thin layers green, and at 75° olive green. This was shown by heating a little of the liquid in a globular flask while it was rapidly rotated by the hand, the liquid thus being spread in a thin layer over a large surface. An examination of this cobalt salt has shown that there are two distinct crystalline hydrates—the one, formed at high temperatures, has the formula $CoI_2 2H_2O$, and is of a dark green colour; the other, which contains a much larger proportion of crystalline water, $CoI_2 6H_2O$, is produced at a low temperature, and its colour is generally brown, in cold weather inclining to red.

The formation of the dihydrate and the anhydrous compound was beautifully shown in the following manner:—A glass plate, upon which was smeared a thin but even layer of the cobalt iodide, was held in the rays of the electric light projected on to a screen. At first nothing was to be seen, but on warming the plate a spot of greenish yellow light appeared, and this spreading in every direction showed itself to be a mass of green crystals; the application of a little more heat soon converted these into the black anhydrous compound.

In the case of didymium nitrate a new line was seen to come into existence. The instances of the third kind were frequently so altered by heat that the less refrangible group of rays was extinguished partially, if not entirely. Cobalt and chromium compounds furnish examples of this.

The formation of different hydrates of the same salt, each of which has its characteristic colour, is very strikingly shown with bromide and iodide of cobalt; thus a sketch of sea and sky is made with the former, the liquid is pink, and not strong in colour, so that very little is seen until the paper be warmed, when the most beautiful azure tints appear. If carefully managed, the green anhydrous compound may be produced, and so give a greenish tinge to the sea. The red hexahydrate of cobalt bromide is first converted into the blue dihydrate, and then into the green anhydrous compound. But an infinitely more astonishing change is that produced by warming a sketch of foliage and water made with the iodide and bromide of cobalt. It has the appearance of a warm-tinted sepia drawing, which gives the foliage quite an autumnal appearance. On warming, the blue of the sky and water, together with exquisite green tints in the foliage, appear. By varying the quantity of the cobalt iodide put on with the brush, colours varying between the most delicate green of spring-time, the full richness of summer, and all kinds of greenish brown autumnal tints, even black, may be produced. The atmospheric moisture re-forms the original hexahydrated salts, and the colours disappear when the paper gets cold again. Two sketches of this kind were exhibited which resumed their original brown colour in the course of half an hour.

It has been suggested, even quite lately, that when a salt such as a chloride is dissolved in water, it is resolved into a hydrochlorate of a metallic oxide, and that hydrated chlorides are always compounds of this kind. Hence, when cobalt chloride is dissolved in water, change from pink to blue might be owing to the alteration in the dissolved compound, from a hydrochlorate of cobalt oxide to a cobalt chloride.

The first step to be taken is the refutation of this. When a solution of cobalt chloride, bromide, or iodide is dissolved in water, and cold alkali, such as potash or soda added, the precipitate formed is not, as one would expect, a hydrate or an oxide, but an oxy-chloride, oxy-bromide, or oxy-iodide, showing that in solution the halogen is still combined with the metal, and is only partially removed by the more powerful base. Similar basic compounds are formed by precipitating other cobalt solutions, such as nitrate.

Equations I. and II. illustrate the supposed and possible decomposing action of water on cobalt chloride, while III. and IV. show the reactions with alkali which would consequently take place; but as these latter do not represent the truth, it necessarily follows that the former are incorrect.

I. $CoCl_2 + H_2O = CoO \cdot 2HCl$.
II. $CoCl_2 + H_2O = CoO + 2HCl$.
III. $CoO \cdot 2HCl + 2KHO = CoO \cdot H_2O + 2KCl + H_2O$.
IV. $CoO + 2HCl + 2KHO = CoO + 2KCl + 2H_2O$.

I. Hence we may conclude that when a salt is dissolved in water it is not decomposed into a mixture of an oxide and an acid, nor does a compound of the oxide with the acid result.

II. When a salt is dissolved in water it does not necessarily attain its maximum state of hydration.

This was long ago suspected by Dr. Gladstone, who, experimenting with cupric chloride, found that a saturated solution of a deep green colour became blue on the addition of water, and this blue became green again upon heating. Furthermore, the blue liquid could be turned to green by the addition of strong hydrochloric acid. These facts of course have been corroborated by spectroscopic observations, and I have succeeded in obtaining others in support of this. Thus the following saturated solutions change colour when diluted with from four to seven times their bulk of water:—

Saturated Solution.	Colour.	Dilute Solution—Colour.
Cupric chloride	Grass green	Blue.
,, bromide	Deep red-brown ..	Yellowish green to azure blue.
Nickel ,,	Dark madder brown	Yellowish green to apple green.
,, iodide	Yellowish brown ..	Yellowish green to apple green.

As illustrations two cylinders were taken, one containing cupric chloride, the other cupric bromide; the former grass green, and the latter deep brown. The colours were shown by swilling the liquid round the sides of the vessels; on dilution with about a quart of water clear azure blue liquids were produced.

A still more striking example is that of the cobalt iodide solution, which is formed by allowing the dihydrate, or the anhydrous salt to deliquesce; it is of a deep green, and on dilution to a very small extent becomes red.

Regnauld and also Person have shown that on diluting a saturated solution of a salt, as a rule there is an absorption of heat. The latter calls this the latent heat of dilution. The former noticed one or two cases in which heat was evolved on dilution. There is every likelihood that this phenomenon is due to the formation of a liquid hydrate. It is impossible of belief that accompanying such a circumstance there should be no measurable development of heat; and these experiments have proved that in all cases when the change of colour consequent on dilution is great, the heat disengaged is very considerable. On diluting a solution of cobalt iodide till the red colour appears, the thermal effect not only registers several degrees on an ordinary thermometer, but it may be perceived by the hand.

The author has not yet completed any exact thermal measurements bearing on this matter, though some experiments have been made in this direction.

III. When a hydrated salt is dissolved in water to form a saturated solution at the ordinary temperature its crystalline molecule remains chemically intact, except in certain exceptional cases when it appears to lose water.

The evidence bearing on this consists of the fact that most solutions of hydrated salt, if saturated, are of the same colour as the solid compound; though in the state of dilute solutions on the one hand, or of partial dehydration on the other, the colour may differ widely from this. In support of this we have the case of cobalt chloride and cobalt iodide, more especially the formation and behaviour of the green solution of the dihydrate of the latter salt. The molecule of the salt is neither hydrated nor dehydrated on solution, otherwise such salts as those named would change colour.

An exceptional phenomenon is marked when cupric chloride, cupric bromide, nickel bromide, and nickel iodide are dissolved in water to saturation. Cupric chloride is a blue salt not deliquescent or liable to absorb water from the air, but rather efflorescent—*i.e.*, apt to part with its water of crystallization; hence, when the blue crystals are dissolved in water they form a deep green liquid, which on dilution becomes azure blue, this azure blue solution by heating again becomes green. The remaining salts are of a yellowish green tint, but on dissolving in as little cold water as possible they give intensely coloured brown liquids. Cupric bromide crystals effloresce, losing 10 per cent. of water and becoming very dark brown, nearly as possible black in colour even in ordinary air, but in presence of moisture they are deliquescent.

Solution facilitates chemical change. Hence, when green cupric bromide crystals are dissolved in water the chemical attraction which binds the one molecule of metallic bromide to the five molecules of water of crystallization is so weakened that the cohesive attraction of the mass of the solvent water overcomes the chemical attraction of the crystalline water, and the resulting liquid is brown. When more water, however, is added, a reversion of this action takes place, and the brown solution becomes green or blue.

IV. When a salt forms two distinct crystalline hydrates, A and B, at temperatures below 100° C., a saturated solution of A will, on heating to 100°, become a solution of B; at intermediate temperatures, a mixture of these two compounds.

This is inferred from the similarity in change of colour of a saline solution to the change of colour in the solid when heated. Bromide and chloride of copper, and, above all, iodide of cobalt, exhibit such changes.

The behaviour of this latter salt, which has been already mentioned, cannot possibly be explained except by the assumption that the hexahydrate, $CoI_2,6H_2O$, exists in the brown solution, and the dihydrate, $CoI_2,2H_2O$, in the green liquid produced from this by heat. The action of heat on cobalt chloride is not so well defined; that it is caused by dehydration we are certain, but whether the compound in solution is the dihydrate or the anhydrous chloride is a matter undetermined. It is not at all unlikely that the blue produced by alcohol is due to the formation of an alcoholate, for the spectrum, though very similar, is not quite identical with that of the hot aqueous solution. An experiment made on the hexahydrate was incidentally confirmatory of the action of water on the cupric chloride and bromide. When this salt was dissolved nearly to saturation in absolute alcohol the liquid had the usual magnificent blue colour; it was put aside under a bell-glass for crystals to separate, these appeared at the bottom of the deep blue liquid to be also of the same colour. When removed, however, and pressed between folds of paper, they had precisely the same composition and red colour as the original salt. Hence, though water could not on solution remove the water of crystallization from the salt, yet alcohol could do this, but on crystallization the original crystalline hydrate was formed, as is the case with cupric chloride and bromide.

V. The effect of heat on what are called the purple chromium solutions is not traced to dehydration, but to a distinct chemical reaction which yields a distinct class of compounds.

The violet or purple compounds of chromium have the general formula $Cr'''R_3{\cdot}xH_2O$, or $Cr_2'''R''_3{\cdot}xH_2O$; when solutions of these in water are heated to 100° C. there is formed a class of substances which may be written thus, $Cr_2'''OR_4{\cdot}xH_2O$, and $Cr_2'''OR''_2{\cdot}xH_2O$, or the first compounds may be said to contain the metal Cr''' as the base of the compound, while the second contains the radical $Cr_2'''O$. This radical I would propose to call chromyl, just as UrO is called uranyl. And it may then be stated, that while the purple compounds are salts of chromium, the green are salts of chromyl.

This conclusion is derived more from the chemical behaviour of these solutions than from their optical properties. Thus green solutions having the same spectrum may be produced from the sulphate or nitrate—(1) by boiling a solution of the purple salt; (2) by dissolving an excess of chromic hydrate in the purple solution; (3) by neutralizing with an alkali one-third of the acid in a solution of the blue salts. 50^{cc} of a boiled solution containing half a gramme of the sulphate or nitrate of chromium will not give a precipitate if boiled with two or three litres of water; but when one third of the acid present has been previously neutralized, or when an excess of chromic hydrate is dissolved in the blue solution, a basic salt is thrown down on boiling with much water. This is exactly the behaviour characteristic of a salt described by Schrötter, to which he assigns the formula $Cr_2O_3 \cdot 2SO_3$, or which may be written $Cr_2O \cdot 2SO_4$. Lœwel describes a similar chloride, which is formed at 100° C.; this he writes thus, $Cr_2O_3 \cdot 4HCl$, and the formula may be modified in the following manner: $Cr_2O \cdot Cl_4 \cdot 2H_2O$. The modification has the following recommendation: that it explains the decomposition of the substance when heated to a high temperature, which Lœwel's formula does not. At or about 300° C. the compound is resolved into a mixture of the anhydrous violet compound of chromium and chlorine, $CrCl_3$, or Cr_2Cl_6, and the anhydrous green oxide, Cr_2O_3; if the original salt were a combination simply of hydrochloric acid with chromic oxide, heating would drive off the volatile acid and leave the oxide only, but the actual change indicates that the chromium and chlorine are in direct combination.

Parliamentary and Law Proceedings.

PHARMACY ACT (IRELAND) BILL.

Second Reading.

In the House of Commons, on Friday, June 18, upon this Bill being reached in the order of the day,—Sir Michael Hicks-Beach said: I ask the indulgence of the House to read this Bill a second time. The object of the Bill is to carry into effect the unanimous recommendations of the Select Committee who inquired into the subject during the last session of Parliament, with the view of establishing in Ireland a Pharmaceutical Society. I believe it is in accordance with the unanimous wish of the inhabitants of that country, in order to meet a crying evil—the want of qualified chemists to compound medicines by law. Objection has been taken to the present measure by the English Pharmaceutical Society on account of its proposing to create reciprocity between the two Societies. I confess that this objection seems to me to be founded on reasonable grounds, and I propose, if the House will allow me to read this Bill a second time, to omit at the next stage of its progress that portion of the Bill which refers to reciprocity between the English and Irish Pharmaceutical Societies. The object we have in view will be met perfectly well in future by leaving each to make rules for its own guidance, and that each should be left to its separate and unfettered action, and I do not believe, so far as regards Ireland, that the Bill will be less effective than at present if the 18th Clause, to which I have referred, is omitted from it. I therefore move the second reading of this Bill, and if that stage is taken now I will go into Committee, *pro formâ* on Monday, and put it in its amended shape as to that particular point, and ample time will be given to those interested to discuss the clauses of the Bill.

Dr. Ward: It seems to me that the omission of the 18th Clause does much to increase an evil that has existed for a long time in reference to the medical profession, viz., the multiplying of bodies to grant qualifications. There are at present nineteen such corporate bodies, which causes unworthy competition between them, for many of them exist only by the fees derivable from the passing of a man, in conferring degrees on candidates before them. This necessarily causes competition, and honourable members will be surprised to hear that the competition becomes so keen as this, that a man when he is rejected by one corporation, say to-day, from the want of sufficient knowledge of his business, from his competing capacity, takes his carpet bag and drives off to some other place and returns home a legal medical practitioner the same week. I have frequently known it done. The 18th Clause proposes to create another corporation—another competing body, simply for money. These corporations are living upon their fees—varying in amount—and the qualifications they give are of no protection whatever to the public, as to the real merits put forward by these corporations. Some of them, no doubt, are very strict, but some are very lax. The Government should deal with this subject as a whole—the medical profession and the branches connected with it. Many propositions have been put forward, but from the jealousy of these corporations and, with all due respect, the ignorance of this House in the matter this great question, goes on year after year without being properly considered and dealt with. We have seen the evils of such a policy in France. I would, if the profession is to continue, as at present, to regulate these matters, appoint a person to attend all these different examinations, and superintend them and see that the public are protected and that the examining boards of the different bodies did not simply pass men merely to earn money for the corporation. This was a question well worthy the attention of a Government that was not going in for learning political questions but sanitary measures. What is the use of making laws for sanitary purposes if there are no men capable of carrying them out? And unless the Government were unable to secure that at least there should be a fair amount of medical information guaranteed by the qualifications granted by these corporations in the way I have mentioned, all these sanitary laws are at least in a very doubtful position. The Government should lessen the grasping powers of these corporations and create a distinct board—a distinct examining body—not for the purpose of obtaining money, but for the protection of the public. I do not, however, oppose the second reading of the Bill.

Mr. Newdegate: On the part of the pharmaceutical chemists in the Midland Counties, I have to thank the right honourable baronet the Chief Secretary for Ireland, for omitting the 18th Clause of the Bill. If the pharmaceutical chemists of Ireland would accept the examinations of the English Pharmaceutical Society, they would be hailed with delight. I have something to do with the Royal Veterinary College. We have strenuously endeavoured to preserve, and we have adhered to the principle of preserving, an examining board for the united body of veterinary surgeons, and a very competent board exists for the purpose. In this case the Pharmaceutical Chemists desire that the same principle should prevail with regard to them, and that if an examining board is to be established for Ireland, it should be on the same terms as that for England, and that they should see what the examinations consist of before it is brought into competition with their own.

Mr. Errington: I will venture to trouble the House for a short time. It was on my motion that the Select Committee was appointed, on whose recommendation this Bill is founded and introduced, and I cannot allow it to pass this stage without acknowledging how much we are indebted to the right honourable baronet the Chief Secretary for Ireland for having framed and brought in this Bill, The Bill as introduced was a very satisfactory measure. The House will understand that this is not a startling or sensational question, but it is considered amongst the professional classes in Ireland, and a large section of the public, a question of considerable importance that this Bill should be passed into a law, as I hope it will be. It will be received in Ireland with satisfaction and pleasure, but I cannot help expressing my regret that the Government should have come to the conclusion of dropping the reciprocity clause. No doubt it is a considerable mutilation of the Bill from its original form, because I feel nothing would be easier when in Committee than to have moulded the clause so as to make it satisfactory to all parties, and especially those whose opposition to the clause has been the cause of its omission from the Bill. We who are anxious that this Bill should pass into a law are also anxious that the rights and interest of the English Pharmaceutical Society should be maintained in the fullest and most ample manner, and this not as a mere matter of policy and justice, but of expediency, because those who are anxious to promote this Bill do it for scientific advantages only and from no desire to reduce that high standard of examination which the Pharmaceutical Society of England has introduced and kept up.

The Bill was then read a second time.

Committee.

On Monday, June 21, Sir Michael Hicks-Beach moved, that the House should go into Committee *pro formâ* on this Bill, in order to allow of the introduction of amendments in accordance with the above undertaking. The Committee ordered the Bill to be reprinted with amendments, and then reported progress. The Bill is to be re-committed on Monday next.

Petitions.

The following petitions against this Bill have been presented in the House of Commons since the 16th inst.:—

Carnarvon ....Mr. William Bulkley Hughes.
Gloucester .... ,, Charles James Monk.
Hertford...............Hon. Henry Frederick Cowper.
Kendal ....Mr. John Whitwell.
Lewes .... ,, William Langham.
Northallerton ...... ,, George William Elliott.
Redditch .... ,, Thomas Eades Walker.
Skipton .... Sir Matthew Wilson, Bart.
Tonbridge .... Mr. Samuel Morley.
Westbury .... ,, Abraham Laverton.

A petition was also presented from North Shields.

CUSTOMS AND INLAND REVENUE ACT.

The Customs and Inland Revenue Act (38 Vict. c. 23), which has received the Royal assent a few days since, contains the following clauses :—

8. In lieu of the duties of excise now payable by law upon or in respect of the licences to be taken out yearly in any part of Great Britain by the owners, proprietors, makers, and compounders of, and persons uttering, vending, or exposing to sale or keeping ready for sale any medicine liable to stamp duty, there shall be paid for each such licence the duty of 5*s*.

9. A licence to a dealer in foreign wine, or to a retailer thereof, shall be granted so as to extend to the sale of any kind of sweets, or made wines, or mead, or metheglin in any quantity, without the payment of any further duty than such as is chargeable on a licence to a dealer in foreign wine, or a retailer thereof.

10. Subject to any regulations which may be from time to time made by the Commissioners of Customs and the Commissioners of Inland Revenue respectively, tinctures or medicinal spirits may be warehoused upon drawback by a licensed rectifier or compounder of spirits in any customs or excise warehouse under the like provisions under which British liqueurs may be so warehoused by virtue of section thirteen of "The Customs and Excise Warehousing Act, 1869."

BOOKS, PAMPHLETS, ETC., RECEIVED.

A DICTIONARY OF CHEMISTRY AND THE ALLIED BRANCHES OF OTHER SCIENCES. By HENRY WATTS, B.A., F.R.S., F.C.S., etc. Second Supplement. London: Longmans, Green, and Co. 1875. From the Publishers.

Notes and Queries.

[441]. GINGERBREAD WORM NUTS.—I beg to inform your correspondent, T. H. W., that I use the following receipt for making gingerbread worm nuts, and that they answer the purpose remarkably well:—

Take of—

Flour	10 ounces.
Sugar	4 ,,
Treacle	4 ,,
Butter	2 ,,
Ginger	2 drachms.
Santonine	3 ,,

Mix and divide into 2 drachm cakes. One to four to be given when fasting, according to age.—E. W. J.

The Irish Pharmacy Bill.

Sir,—I read with much interest your able article on this subject in the *Pharmaceutical Journal* of last week, and I have since learned from the report of Sir Michael Hicks-Beach's speech on moving the second reading of the Bill, that he so far deferred to the objections taken by the Pharmaceutical Society of Great Britain as to abandon the 18th Clause, which would have compelled our Registrar to place the names of men who had passed the examination to be instituted in Ireland on the Register of Great Britain. I know well enough that it is the declared intention of the promoters of the separate system for Ireland to institute an examination equal to our own "Major;" but setting aside the too common fate of "good intentions," and without the smallest doubt of their genuineness, I venture to think it was rightly decided to oppose the admission of men over whose examination our Council have no control to the register of which they are the guardians. The preamble of the Bill sets forth a want of dispensers in Ireland as the ground of its necessity. This want is undisputed, and the natural fear is that to meet it candidates will not be subjected to too severe an ordeal. In justification of this fear it is scarcely necessary to look further than to the commencement of our own Society and its progress in the natural growth of its examinations from that time to the present. Under any circumstances the candidate who passes one examination, into which the whole subjects with which he is required to be conversant are condensed, cannot fairly be looked on as equal to one who has passed at intervals the "Preliminary," "Minor," and "Major." And here, sir, let it be remembered that the one examination proposed is to entitle a man to the highest grade in the business, that of "Pharmaceutical Chemist." It is this consideration which urges me to address you, and through you the pharmaceutical chemists of Great Britain, that they may be aroused to a threatened danger. The withdrawal of the reciprocity clause must, of course, remove a great objection but not the only one to the proposed measure. You very properly draw attention to the appropriation of our highest title, a title which was exclusively accorded to a certain class of men in Great Britain, and has been carefully guarded there for many years, to other men not designated by the Acts of Parliament already in existence, living side by side with us in the sister kingdom. It seems to me that notwithstanding the sea which rolls between Great Britain and Ireland, they are virtually one kingdom, and year by year distinctions which have existed between them disappear, and will, I hope, continue to disappear. Descriptive titles in the one country will be considered by the public to be of equal value in the other, and should rightly have the same value. A physician in Ireland or Scotland is a physician in England, but the medical council which registers has also the power to enforce the proper examination in the three countries, and therefore the public are justified in valuing the degrees of the three countries alike. There is really no advantage to Ireland in describing her examined men by the same title as the English. Her want is an increase of the chemists qualified to dispense medicines, and the most intelligible description of them would be "dispensing chemists." You will remark that these men will have greater advantages secured to them than we have, for no unregistered men will be allowed even to compound medicines from medical prescriptions, a concession the chemists of England vainly tried to obtain.

By the notices placed on the paper of the House of Commons, it appears that Mr. Thomas Cave intends to move the exchange of title from "Pharmaceutical Chemist" to "Dispensing Chemist," and I earnestly trust that every chemist will urge his representative in Parliament to support this amendment and thereby prevent a depreciation of the title which is the highest object of our ambition.

Ph. Chemist.

Sir,—My attention having been directed to a leading article in the *Pharmaceutical Journal* of June 12th, on the Pharmacy Act (Ireland) Bill, I beg to correct some errors which exist in it as regards the action of the King and Queen's College of Physicians, and of Sir D. J. Corrigan, with respect to the question of pharmacy in Ireland.

1. With regard to the "singular inconsistency" which you attribute to this College, in that the College has presented a petition to Parliament in favour of the Pharmacy Bill. I may state that the College has felt itself perfectly free to take such action as seemed to it best for the interests of pharmacy in Ireland, inasmuch as the Bill which the College drew up in 1874, for extending to Ireland the Pharmacy Act of 1868, did not meet with the favour or support the College had hoped for it, and inasmuch as it was reported against (as you properly state) by the Select Committee of the House.

2. Sir D. J. Corrigan in giving evidence before the Select Committee of the House of Commons on July 13th, 1874 (*vide* page 33 of the Report, queries 548, 549) stated that the Bill (of the College) represented the views of this College and his own views to a great extent.

3. Sir D. J. Corrigan is, in the article referred to, incorrectly designated as "the President of the College," whereas he was not President last year, nor is he now; he is one of the Ex-Presidents of the College, not having held that office since 1863.

J. Magee Finny, M.D.,
Fellow and Registrar.

King and Queen's College of Physicians in Ireland, Dublin, June 17, 1875.

[*** We by no means presume to dispute the perfect freedom of the King and Queen's College of Physicians to change its opinions or its action in reference to pharmacy, even to the extent of petitioning Parliament in favour of a Bill that proposes to do the very opposite of what the College not long since took much pains to prove was the proper course; but at the same time we cannot admit that in pointing out such "singular inconsistency" we are falling into error that needs correction. This inconsistency is matter of record, as will be evident on refering to the circular of the King and Queen's College (see *Pharmaceutical Journal, ante*, p. 995). As regards the position of Sir Dominic Corrigan as President of the College, and his evidence, the following quotation from the Report of the Select Committee will speak for itself, and show that he acted as the representative of the College:—

"546. I think you hold, or have held, some office in connection with the College of Physicians in Dublin?—Yes, the office of President.

"547. *And in that capacity you have taken considerable interest in the Bill which is now before the Committee?—I have.*

"548. I believe that the Bill represents the views of the College of Physicians, does it not?—It does.

"549. And your own views, I suppose?—It represents my own views to a great extent; but not altogether."

But notwithstanding this, the evidence given by Sir Dominic was totally opposed to the Bill.—Ed. Ph. Journ.]

Drugging of Animals Bill.

Sir,—Whatever may have become of Sir J. Astley's Bill before your next issue, its success at present seems desirably doubtful. Immediately upon reading its text, in common with some of my neighbours and friends (our local secretary being unfortunately confined to his bed) I communicated with three Members of Parliament, belonging to various political parties, and their opinion was unanimously against the measure, as I am persuaded the overwhelming majority of the House will be, should it ever come to a division. Indeed it is difficult to write seriously about the Bill. But as some seem to have given it serious, if modified, approval perhaps you will allow me to state one or two objections to it, which I will do as soberly as I can.

In the preamble I object to the word "whereas" which gives it a legislative form. It may be desirable to prevent the practice of administering "poisonous drugs and other compounds to horses and other animals," but the case of the assumption that an evil existing, an Act of Parliament is the remedy, is somewhat amusing. It is highly desirable to prevent a great many other things, and we are in danger of being governed overmuch. If we have a weakness for an established church, we must worship high heaven by a "Reglation Act," and while, I believe, the elevation of the "elements" above the head is illegal, I am not sure that a "priest" may not place his head below the "elements," he may "genuflect" but not kneel. To such attenuations do Acts of Parliament tend.

I entertain strong objections to the first clause because it is unnecessary and unduly stringent. The agricultural labourer and the other parties affected are servants, and as everybody in the country knows, the power of a master is sufficiently absolute already. Did any of your readers ever follow a discharged carter in search of employment? But as the countryman will take care of himself in the coming time of his enfranchisement, and as these two objections are partially political, and to that extent unsuitable for your pages, I would only remark that it cannot have escaped the notice of chemists that under this clause if they, not being M.R.C.V.S., should advise a groom, bailiff or servant to administer to a "horse or other animal" any of the poisons in the schedule—the consent of the owner being in many cases of emergency quite impossible to obtain—they will have induced such servant to commit a misdemeanour, for which his master may prosecute them or not, at will.

But the main objections of chemists lie against the third clause. The remedy is out of all proportion to the evil. The manifold uses of the "poisons" now for the first time introduced, and the impracticability of registering the sale of them, as well as of poisons in part II. of the schedule of the existing Pharmacy Act, constitute difficulties too well understood by persons engaged in business to need remark. The proposition vexatiously to interfere with the daily domestic and trade avocations of the overwhelming town population to prevent the poisoning or injury of a few agricultural horses is as ridiculous as making the roasting fire revolve around the joint. Absurd as is the suggestion, the issuing of a licence to Hodge to purchase "poisons," as we receive permits to buy S. V. M., would be simplicity in comparison.

But a stronger objection still is that the tendency of the Bill is to make chemists spies and informers, without however any efficient provision for ensuring even this result. I am not an apologist for the "Pharmacy Act," but its object, in the main, with the exception of cantharides, savin, and ergot, is to prevent innocent mistakes. The object of this Bill is to catch criminals who are produced by the Bill. Supposing the Bill passed and the "poison" duly registered, is the country "Ph. C." going to touch his hat to the squire and hand over his register on demand? Some time ago a sprig of the "upper ten" asked me if I had sold any poison lately. I said "Certainly." "To whom?" (I think he said "who to?") I declined to answer, which rather excited the young gentleman, who intimated that he should apply to the superintendent of police, whose advice I urged him to seek, with the further assurance that to neither of them would I divulge any transactions with the next door neighbour of his pigs or other "pet game," any more than I would say whether his sister bought hair dye, or himself capsules, and I have not the pain of knowing a chemist who would be less independent. But if the poison registers are to be private (without which no customer will sign them), and if there is no means of getting at their contents (as I trust there never will be), except a charge against the chemist of violating the Act, I suppose the chemist with his register is to serve the purpose in the stable to which the devil and his appliances are sometimes put in the church—to frighten Hodge into good behaviour.

Further, another class of poison vendors would be created, and that argument might have weight in some quarters. It is not proposed to confine the sale of poisons in part II. of the schedule to chemists. Personally I do not care to raise my voice against that. It requires no high qualification to retail oil of vitriol and spirit of salt, nor any great scholarship to register the transaction. I have no desire to defend exclusive privileges of any kind. And perhaps I may be allowed to wander from my subject to remark that though we may use our mystic initials to influence the public *quantum valeant*, when a man has been in business a dozen years he will have found the true contraction for "Pharmaceutical Chemist," or any other title in the estimation of the public at just about what he is worth.

The principal subject of my letter is not a great one. I have only touched it, but already I have trespassed to largely on your space.

HENRY H. POLLARD

Ryde, June 21, 1875

OFFICIAL *v.* OFFICINAL.

Sir,—It may please some of your readers to follow up the question of "Official" and "Officinal" to a classical period. I send you a few illustrations of "Officinal" (workshop) and (drug-shop) "Venenum," "Maleficum," where poison was concocted by Canidia, whom Horace so designates.

"Jam Cytherea choros ducit Venus, imminente Luna :
Junctæque Nymphis Gratiæ decentes
Alterno terram quatiunt pede, dum graves Cyclopum
Vulcanus ardens urit 'officinas.'"

Horace, Ode IV. to Sestius.

"—— Tu, donec cinis
Injuriosis aridus ventis ferar,
Cales venenis 'officina' Colchicis."

Horace, Epode 17.

JOHN FREDK. STANFORD.

* The witch (Canidia) is made herself to be a poison or drug-shop.

"*Holcus*."—*Arrhenatherum elatius, β. bulbosum* and *Glyceria fluitans*.

G. S. Druce.—(1) *Trisetum flavescens* ; (2) *Holcus mollis* ; (3) *Aira cæspitosa*.

G. Watt.—(2) *Ranunculus Flammula* ; (5) *Fumaria officinalis*. The other specimens are correctly named.

"*Beta*."—No.

H. A. K.—(1) The direction for the preliminary heating of the oil is in accordance with the result of the experiments of M. Méhu, who found that by thus previously removing water and certain unstable organic substances from the oil, a solution of phosphorus in almond oil will remain clear and unaltered. See vol. iii. of present series, p. 412. (2) No doubt "Sal aëratus" is intended.

Y. Z.—Carbonate of baryta is not included in the schedule of poisons under the Pharmacy Act.

J. Burt.—A letter addressed to the India Museum would reach the gentleman mentioned.

R. H. M.—The question has been already carefully considered, and the conclusion arrived at that such a plan as suggested by you could not be carried out satisfactorily and usefully in the columns of a weekly journal.

W. R. F.—We think that the sale of quinine wine not prepared and sold as the B. P. article, would require a sweet wine licence, or even under certain conditions might necessitate the use of a stamp. The safest plan would be to submit the question to the Inland Revenue authorities.

J. Gray.—(*a*) *Potentilla* (probably *P. recta*, but leaves are not sent), not British; (*b*) *Gladiolus communis*, not British; (*c*) *Chrysanthemum leucanthemum* ; (*d*) *Rhinanthus Crista-galli* ; (*e*) *Geranium dissectum* ; (*f*) *Stachys sylvatica* ; (*g*) *Holcus lanatus* ; (*h*) *Geranium Robertianum* ; (*i*) Too imperfect to name; (*k*) *Potentilla anserina* ; (*l*) *Matricaria Parthenium* ; (*m*) *Dactylis glomerata* ; (*n*) *Plantago lanceolata*. We cannot undertake to give the names of exotic species or varieties.

H. Stewart.—A species of *Spiræa*. It is impossible to identify it without leaves. Inflorescence a panicle.

"*Minor*" is thanked for his communication.

J. S.—The following is the formula of the Spiritus Ammoniæ Aromaticus of the U.S.P. :—

Take of Carbonate of Ammonium a troyounce ;
Water of Ammonia three fluidounces ;
Oil of Lemon two fluidrachms and a half ;
Oil of Nutmeg forty minims ;
Oil of Lavender fifteen minims ;
Alcohol a pint and a half ;
Water a sufficient quantity.

Dissolve the carbonate in the water of ammonia, previously mixed with four fluidounces of water. Dissolve the oils in the alcohol, mix the two solutions, and add sufficient water to make the whole measure two pints.

"*A Country Druggist*."—The preparation is a proprietary article.
